Preface

Once men turned their thinking over to machines in the hope that this would set them free. But that only permitted other men with machines to enslave them. — Frank Herbert, Dune, 1965

You can let your smart devices decide what you should see and think, or you can understand how they work.

Make your choice.

Timetable and lecture rooms

Due to the current situation regarding the Covid-19 pandemic, practicals will take place ONLINE this year. They will be held on Mondays from 14:30 to 16:30 and on Wednesdays from 11:30 to 12:30.

Practicals will use the Zoom platform (<https://zoom.us/>) and the link for the connection will be published on the practical page available in this site a few minutes before the start of the session.

This first part of the course will tentatively run from Wednesday, September 23rd, 2020 to Monday, November 2nd, 2020.

.1 Moodle

In the [Moodle](#) page of the course³ you can find announcements and videos of the lectures.

.2 Zoom links

The zoom links for the practicals can be found in the [announcement on Moodle](#)⁴

News

Friday 24 November 2020: vastly updated Complexity worksheet and renamed to [Algorithm analysis and recursive functions](#)

Friday 6 November 2020: published [midterm A solutions](#)

Tuesday 3 November 2020: published [midterm simulation solutions](#)

Thursday 22 October 2020: A TUTORING SERVICE for data science studentes has been set up, see announcement on Moodle⁵

WARNING: Part A of this website is being gradually improved and transferred to [en.softpython.org](#)⁶

Keep an eye on news to see what has been transferred so far. Whenever a page is moved, I will substitute the old page with a link.

MOVED SO FAR:

- introduction to [Overview](#)⁷, [Installation](#)⁸, [Tools and scripts](#)⁹
- basics to [Basics](#)¹⁰
- split strings into [Strings1 - Introduction](#)¹¹, [Strings2 - Operators](#)¹² and [Strings3 - Methods](#)¹³ (a fourth page remains to be added)
- split lists into [Lists1 - Introduction](#)¹⁴, [Lists2 - Operators](#)¹⁵ and [Lists3 - Methods](#)¹⁶ (a fourth page remains to be added)
- tuples to [Tuples](#)¹⁷
- sets to [Sets](#)¹⁸
- split dictionaries into [Dictionaries1 - Introduction](#)¹⁹, [Dictionaries2 - Operators](#)²⁰ and [Dictionaries3 - Methods](#)²¹ (a fourth and fifth pages remains to be added)
- split control flow into [Control flow 1 - if](#)²², [Control flow 2 - for](#)²³ and [Control flow 3 - while](#)²⁴
- Error handling and testing: moved exceptions and assert parts to [Error handling and testing](#)²⁵

**CHAPTER
ONE**

OVERVIEW

1.1 Slides

See *Slides page*

1.2 Office hours

To schedule a meeting, see here³⁵

1.3 Labs timetable

For the regular labs timetable please see:

- Part A: Andrea Passerini's course site³⁶
- Part B: Luca Bianco's course site³⁷

1.4 Tutoring

A tutoring service for Scientific Programming has been set up, see [Moodle announcement](#)³⁸

Please take advantage of it as much as possible so you don't end up writing random code at the exam!

³⁵ <http://www.davidleoni.it/office-hours>

1.5 References

- Source code³⁹ of these worksheets, ([download HTML zip⁴⁰](#))

1.5.1 Part A References

- Part A Theory slides⁴¹ by Andrea Passerini
- See References on SoftPython website⁴²

1.5.2 Part B References

See *Sciprog References page*

1.5.3 Editors

- Visual Studio Code⁴³: the course official editor.
- Spyder⁴⁴: Seems like a fine and simple editor
- PyCharm Community Edition⁴⁵
- Jupyter Notebook⁴⁶: Nice environment to execute Python commands and display results like graphs. Allows to include documentation in Markdown format
- JupyterLab⁴⁷ : next and much better version of Jupyter, although as of Sept 2018 is still in beta
- PythonTutor⁴⁸, a visual virtual machine (*very useful!* can also be found in examples inside the book!)

1.5.4 Further readings

- Rule based design⁴⁹ by Lex Wedemeijer, Stef Joosten, Jaap van der woude: a very readable text on how to represent information using only binary relations with boolean matrices (not mandatory read, it only gives context and practical applications for some of the material on graphs presented during the course)

1.6 Exams

Exams dates: see Moodle⁵⁰

1.6.1 Past exams

- *Past exams page*

1.6.2 Exam modalities

Make practice with the lab computers !!

Exam will be in Linux Ubuntu environment (even when online) - so learn how to browse folders there and if in presence also typing with noisy lab keyboards :-)

Sciprog exams are open book. You will only be given access to this documentation (if in presence you can also bring a printed version of the material listed below):

- Sciprog lab website⁵¹
- Andrea Passerini slides⁵² and Luca Bianco slides
- Python 3 documentation⁵³
 - In particular, Unittest docs⁵⁴
 - If you need to look up some Python function, please start today learning how to search documentation on Python website.
- Part A: Think Python⁵⁵ book
- Part B: Problem Solving with Algorithms and Data Structures using Python⁵⁶ book

1.6.3 Expectations

This is a data science master, so you must learn to be a proficient programmer - no matter the background you have.

Exercises proposed during labs are an example of what you will get during the exam, BUT **there is no way you can learn the required level of programming only doing exercises on this website or softpython**. Fortunately, since Python is so trendy nowadays there are a zillion good resources to hone your skills - you can find some in *Resources*

To successfully pass the exam, you should be able to quickly solve exercises proposed during labs with difficulty ranging from \oplus to $\oplus\oplus\oplus$ stars. By quickly I mean in half an hour you should be able to solve a three star exercise $\oplus\oplus\oplus$. Typically, an exercise will be divided in two parts, the first easy $\oplus\oplus$ to introduce you to the concept and the second more difficult $\oplus\oplus\oplus$ to see if you really grasped the idea.

Before getting scared, keep in mind I'm most interested in your capability to understand the problem and find your way to the solution. In real life, junior programmers are often given by senior colleagues functions to implement based on specifications and possibly tests to make sure what they are implementing meets the specifications. Also, programmers

⁵⁰ <https://didatticaonline.unitn.it/dol/course/view.php?id=25445>

⁵¹ <https://sciprog.davidleoni.it>

⁵² <http://disi.unitn.it/~passerini/teaching/2019-2020/sci-pro/>

⁵³ <https://docs.python.org/3/>

⁵⁴ <https://docs.python.org/3/library/unittest.html>

⁵⁵ <https://runestone.academy/runestone/static/thinkcspy/index.html>

⁵⁶ <https://runestone.academy/runestone/static/pythonds/index.html>

copy code all of the time. This is why during the exam I give you tests for the functions to implement so you can quickly spot errors, and also let you use the course material (see [exam modalities](#)).

Part A expectations: performance does *not* matter: if you are able to run the required algorithm on your computer and the tests pass, it should be fine. Just be careful when given a 100Mb file, in that case sometimes bad code may lead to very slow execution and/or clog the memory.

In particular, in lab computers the whole system can even hang, so watch out for errors such as:

- infinite `while` which keeps adding new elements to lists - whenever possible, prefer `for` loops
- scanning a big pandas dataframe using a `for in` instead of pandas native transformations

Part B expectations: performance *does* matter (i.e. finding the diagonal of a matrix should take a time linearly proportional to n , not n^2). Also, in this part we will deal with more complex data structures. Here we generally follow the *Do It Yourself* method, reimplementing things from scratch. So please, use the brain:

- if the exercise is about *sorting*, *do not* call Python `.sort()` method !!!
- if the exercise is about data structures, and you are thinking about converting the whole data structure (or part of it) into python lists, *first*, think about the computational cost of such conversion, and *second*, do ask the instructor for permission.

1.6.4 Grading

Taking part to an exam erases *any* vote you had before (except for Midterm B which of course doesn't erase Midterm A taken in the same academic year)

Correct implementations: Correct implementations with the required complexity grant you full grade.

Partial implementations: Partial implementations *might* still give you a few points. If you just can't solve an exercise, try to solve it at least for some subcase (i.e. array of fixed size 2) commenting why you did so.

When all tests pass hopefully should get full grade (although tests are never exhaustive!), but if the code is not correct you will still get a percentage. Percentage of course is *subjective*, and may depend on unfathomable factors such as the quantity of jam I found in the morning croissant that particular day. Jokes aside, the percentage you get is usually inversely proportional to the amount of time I spend fixing your algorithm.

After exams I publish the code with corrections. If all tests pass and you still don't get 100% grade, you may come to my office questioning the grade. If tests *don't* pass I'm less available for debating - I don't like much complaints like 'my colleague did the same error as me and got more points' - even worse is complaining without having read the corrections.

1.6.5 Exams FAQ

First and foremost, I'm not the boss here, please refer to exam rules explained by [Andrea Passerini](#)⁵⁷ slides.

I add here some further questions I sometimes receive - luckily, answers are pretty easy to remember.

I did good part A/B, can I only do part B/A on next exam?

No way.

Can I have additional retake just for me?

No way.

Can I have additional oral to increase the grade?

No way.

⁵⁷ <http://disi.unitn.it/~passerini/teaching/2020-2021/sci-pro/slides/00-introcorso.pdf>

I have $7 + \sqrt{3}$ INF credits from a Summer School in Applied Calculonics, can I please give only Part B?

I'm not into credits engineering, please ask the administrative office or/and Passerini.

I have another request which does not concern corrections / possibly wrong grading

I'm not the boss, ask Passerini.

I've got 26.99 but this is my last exam and I really need 27 so I can get good master final outcome, could you please raise the grade of just that little 0.01?

Preposterous requests like this will be forwarded to our T-800 assistent, it's very efficient :

1.6.6 Exams How To

Make sure all exercises at least compile!

Don't forget duplicated code around!

If I see duplicated code, I don't know what to grade, I waste time, and you don't want me angry while grading.

Only implementations of provided function signatures will be evaluated !!

For example, if you are given to implement:

```
def f(x):
    raise Exception("TODO implement me")
```

and you ship this code:

```
def my_f(x):
    # a super fast, correct and stylish implementation

def f(x):
    raise Exception("TODO implement me")
```

We will assess only the latter one `f(x)`, and conclude it doesn't work at all :P !!!!!!

Helper functions

Still, you are allowed to define any extra helper function you might need. If your `f(x)` implementation calls some other function you defined like `my_f` here, it is ok:

```
# Not called by f, will get ignored:  
def my_g(x):  
    # bla  
  
# Called by f, will be graded:  
def my_f(y,z):  
    # bla  
  
def f(x):  
    my_f(x, 5)
```

1.6.7 How to edit and run

Look in *Applications->Programming*:

- Part A: **Jupyter**: open Terminal and type `jupyter notebook`
- Part B: open **Visual Studio Code**

If for whatever reason tests don't work in Visual Studio Code, be prepared to run them in the Terminal.

PAY close attention to function comments!

DON'T modify function signatures! Just provide the implementation

DON'T change existing test methods. If you want, you can add tests

DON'T create other files. If you still do it, they won't be evaluated

1.6.8 Debugging

If you need to print some debugging information, you are allowed to put extra print statements in the function bodies

Even if print statements are allowed, be careful with prints that might break your function! For example, avoid stuff like this:

```
x = 0  
print(1/x)
```

**CHAPTER
TWO**

PAST EXAMS

2.1 Data science

NOTE: 19-20 exams are very similar to 18-19, the only difference being that **you might also get an exercise on Pandas.**

2.1.1 Midterm Sim - Tue 13, Nov 2018

Scientific Programming - Data Science Master @ University of Trento

Download exercises and solution

Introduction

- This simulation gives you **NO credit whatsoever, it's just an example**. If you do everything wrong, you lose nothing. If you do everything correct, you gain nothing.

What to do

- 1) Download `sciprogs-ds-2018-11-13-exam.zip` and extract it on your desktop. Folder content should be like this:

```
sciprogs-ds-2018-11-13-FIRSTNAME-LASTNAME-ID
A1.ipynb
A2.ipynb
B1.py
B1_test.py
B2.py
B2_test.py
jupman.py
sciprogs.py
```

- 2) Rename `sciprogs-ds-2018-11-13-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprogs-ds-2018-11-12-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins. If it takes longer, leave it and try another exercise.

1. matrices

(continued from previous page)

1.2 lab

⊕⊕⊕ If you're a teacher that often see new students, you have this problem: if two students who are friends sit side by side they can start chatting way too much. To keep them quiet, you want to somehow randomize student displacement by following this algorithm:

1. first sort the students alphabetically
2. then sorted students progressively sit at the available chairs one by one, first filling the first row, then the second, till the end.

Now implement the algorithm:

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

data-jupman-show="Show solution"

data-jupman-hide="Hide">Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[3]: def lab(students, chairs):
    """
        INPUT:
        - students: a list of strings of length <= n*m
        - chairs: an nxm matrix as list of lists filled with None values (empty_
        ↪chairs)

        OUTPUT: MODIFIES BOTH students and chairs inputs, without returning anything

        If students are more than available chairs, raises ValueError

        Example:

        ss = ['b', 'd', 'e', 'g', 'c', 'a', 'h', 'f' ]

        mat = [
            [None, None, None],
            [None, None, None],
            [None, None, None],
            [None, None, None]
        ]

        lab(ss, mat)

        # after execution, mat should result changed to this:

        assert mat == [
            ['a', 'b', 'c'],
            ['d', 'e', 'f'],
            ['g', 'h', None],
            [None, None, None],
        ]
        # after execution, input ss should now be ordered:

        assert ss == ['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h']

        For more examples, see tests
    
```

(continues on next page)

(continued from previous page)

```
"""

n = len(chairs)
m = len(chairs[0])

if len(students) > n*m:
    raise ValueError("There are more students than chairs ! Students = %s, chairs = %sx%s" % (len(students), n, m))

i = 0
j = 0
students.sort()
for s in students:
    chairs[i][j] = s

    if j == m - 1:
        j = 0
        i += 1
    else:
        j += 1

```

2. phones

A radio station used to gather calls by recording just the name of the caller and the phone number as seen on the phone display. For marketing purposes, the station owner wants now to better understand the places from where listeners where calling. He then hires you as Algorithmic Market Strategist and asks you to show statistics about the provinces of the calling sites. There is a problem, though. Numbers where written down by hand and sometimes they are not uniform, so it would be better to find a canonical representation.

NOTE: Phone prefixes can be a very tricky subject, if you are ever to deal with them seriously please use proper phone number parsing libraries⁶⁵ and do read [Falsehoods Programmers Believe About Phone Numbers](#)⁶⁶

2.1 canonical

⊕ We first want to canonicalize a phone number as a string.

For us, a canonical phone number:

- contains no spaces
- contains no international prefix, so no +39 nor 0039: we assume all calls where placed from Italy (even if they have international prefix)

For example, all of these are canonicalized to “0461123456”:

```
+39 0461 123456
+390461123456
0039 0461 123456
00390461123456
```

These are canonicalized as the following:

⁶⁵ <https://github.com/daviddrysdale/python-phonenumbers>

⁶⁶ <https://github.com/googlei18n/libphonenumber/blob/master/README.md>

328 123 4567	->	3281234567
0039 328 123 4567	->	3281234567
0039 3771 1234567	->	37711234567

REMEMBER: strings are immutable !!!!

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

data-jupman-show="Show solution" data-jupman-hide="Hide">Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[4]: def canonical(phone):
    """ RETURN the canonical version of phone as a string. See above for an
    ↪explanation.
    """

    p = phone.replace(' ', '')
    if p.startswith('0039'):
        p = p[4:]
    if p.startswith('+39'):
        p = p[3:]
    return p

assert canonical('+39 0461 123456') == '0461123456'
assert canonical('+390461123456') == '0461123456'
assert canonical('0039 0461 123456') == '0461123456'
assert canonical('00390461123456') == '0461123456'
assert canonical('003902123456') == '02123456'
assert canonical('003902120039') == '02120039'
assert canonical('0039021239') == '021239'
```

</div>

```
[4]: def canonical(phone):
    """ RETURN the canonical version of phone as a string. See above for an
    ↪explanation.
    """

    raise Exception('TODO IMPLEMENT ME !')

assert canonical('+39 0461 123456') == '0461123456'
assert canonical('+390461123456') == '0461123456'
assert canonical('0039 0461 123456') == '0461123456'
assert canonical('00390461123456') == '0461123456'
assert canonical('003902123456') == '02123456'
assert canonical('003902120039') == '02120039'
assert canonical('0039021239') == '021239'
```

2.2 prefix

⊕⊕ We now want to extract the province prefix - the ones we consider as valid are in `province_prefixes` list.

Note some numbers are from mobile operators and you can distinguish them by prefixes like 328 - the ones we consider are in `mobile_prefixes` list.

Show solution</div><div class="jupman-sol jupman-sol-code" style="display:none">

```
[5]: province_prefixes = ['0461', '02', '011']
mobile_prefixes = ['330', '340', '328', '390', '3771']

↪ '02 423', '02 424']) == {'0461':2, 'mobile':1, '02':3}
```

2.4 display calls by prefixes

⊕⊕ Using matplotlib, display a bar plot of the frequency of calls by prefixes (including mobile and unrecognized), sorting them in reverse order so you first see the province with the higher number of calls. Also, save the plot on disk with plt.savefig('prefixes-count.png') (call it before plt.show())

If you're in trouble you can find plenty of examples in the visualization chapter⁶⁷

You should obtain something like this:

⁶⁷ <https://sciprog.davidleoni.it/visualization/visualization-sol.html>

[7]:

```
%matplotlib inline
import numpy as np
import matplotlib.pyplot as plt
province_prefixes = ['0461', '02', '011']
mobile_prefixes = ['330', '340', '328', '390', '3771']
phones = ['+39 02 423', '0461123', '02 426', '+39 0461 4321', '0039328 1234567',
          '02 423', '02 424']

# write here
```

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

[8]: # SOLUTION

```
%matplotlib inline
import numpy as np
import matplotlib.pyplot as plt

province_prefixes = ['0461', '02', '011']
province_names = ['Trento', 'Milano', 'Torino']
mobile_prefixes = ['330', '340', '328', '390', '3771']
phones = ['+39 02 423', '0461123', '02 426', '+39 0461 4321', '0039328 1234567',
          '02 423', '02 424']

coords = list(hist(phones).items())

coords.sort(key=lambda x:x[1], reverse=True)

xs = np.arange(len(coords))
ys = [c[1] for c in coords]
```

(continues on next page)

(continued from previous page)

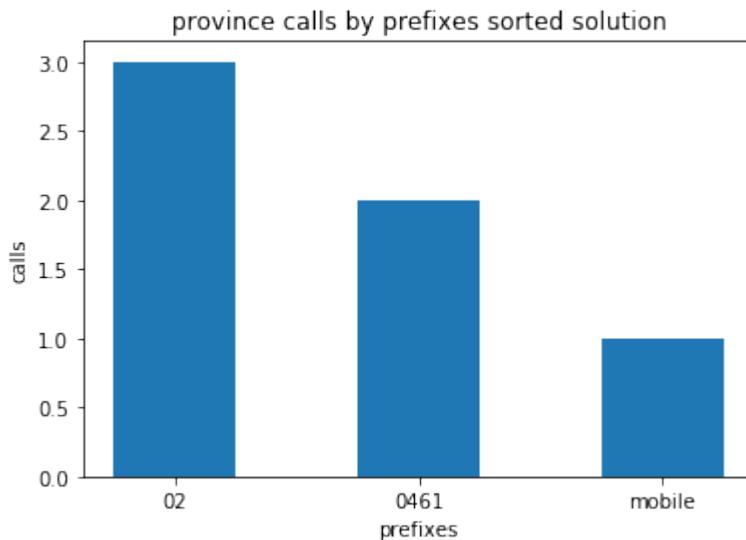

```
plt.bar(xs, ys, 0.5, align='center')

plt.title("province calls by prefixes sorted solution")
plt.xticks(xs, [c[0] for c in coords])

plt.xlabel('prefixes')
plt.ylabel('calls')

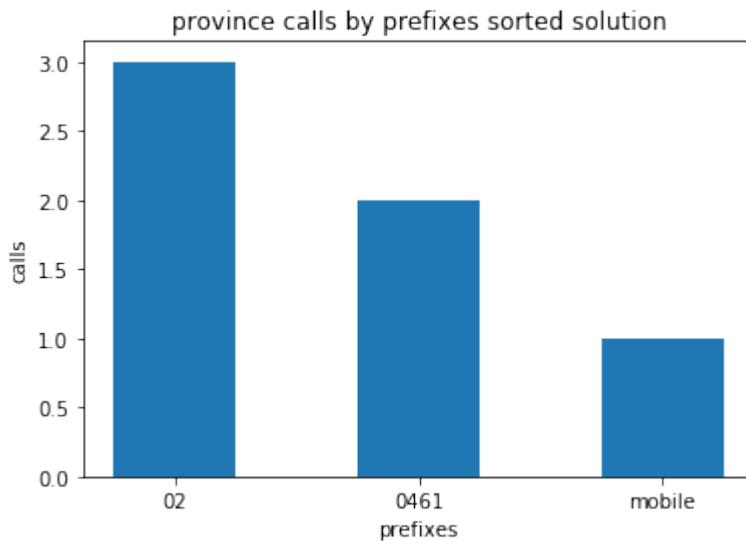

plt.savefig('prefixes-count-solution.png')

plt.show()
```

</div>

2.1.2 Midterm - Fri 16 Nov 2018

Scientific Programming - Data Science Master @ University of Trento

Download exercises and solution

Introduction

What to do

- 1) Download `sciprog-ds-2018-11-16-exam.zip` and extract it on your desktop. Folder content should be like this:

```
sciprog-ds-2018-11-16-FIRSTNAME-LASTNAME-ID  
exam-2018-11-16.ipynb  
jupman.py  
sciprog.py
```

- 2) Rename `sciprog-ds-2018-11-16-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2018-11-16-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise.
- 4) When done:

if you have unitn login: zip and send to examina.icts.unitn.it⁶⁸

If you don't have unitn login: tell instructors and we will download your work manually

A1 union

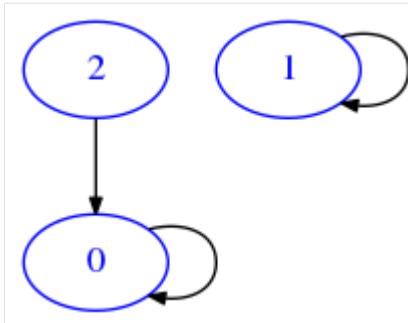

⊕⊕ When we talk about the *union* of two graphs, we intend the graph having union of vertices of both graphs and having as edges the union of edges of both graphs. In this exercise, we have two graphs as list of lists with boolean edges. To simplify we suppose they have the same vertices but possibly different edges, and we want to calculate the union as a new graph.

For example, if we have a graph `ma` like this:

```
[2]:  
ma = [  
        [True, False, False],  
        [False, True, False],  
        [True, False, False]  
    ]
```

```
[3]: draw_mat(ma)
```

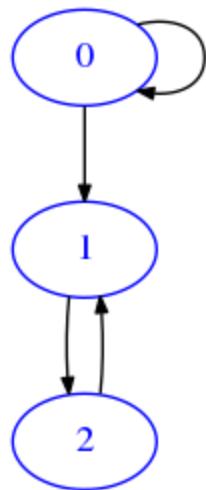

⁶⁸ <http://examina.icts.unitn.it>

And another mb like this:

```
[4]: mb = [
    [True, True, False],
    [False, False, True],
    [False, True, False]
]
```

```
[5]: draw_mat(mb)
```

The result of calling `union(ma, mb)` will be the following:

```
[19]: res = [[True, True, False], [False, True, True], [True, True, False]]
```

which will be displayed as

```
[20]: draw_mat(res)
```

So we get same vertices and edges from both ma and mb

[Show solution](#)<div class="jupman-sol jupman-sol-code" style="display:none">

```

A2 surjective

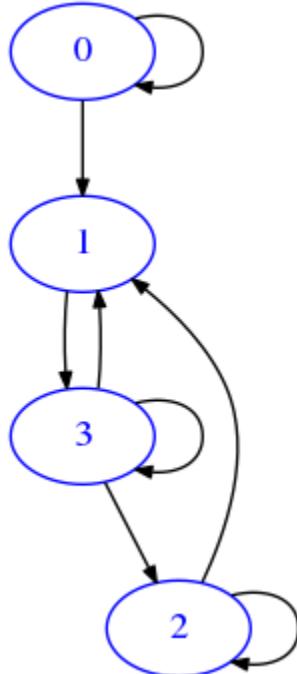

⊕⊕ If we consider a graph as a nxn binary relation where the domain is the same as the codomain, such relation is called *surjective* if every node is reached by *at least* one edge.

For example, G1 here is surjective, because there is at least one edge reaching into each node (self-loops as in 0 node also count as incoming edges)

```
[7]: G1 = [
    [True, True, False, False],
    [False, False, False, True],
    [False, True, True, False],
    [False, True, True, True],]

]
```

```
[8]: draw_mat(G1)
```

G2 down here instead does not represent a surjective relation, as there is *at least* one node (2 in our case) which does not have any incoming edge:

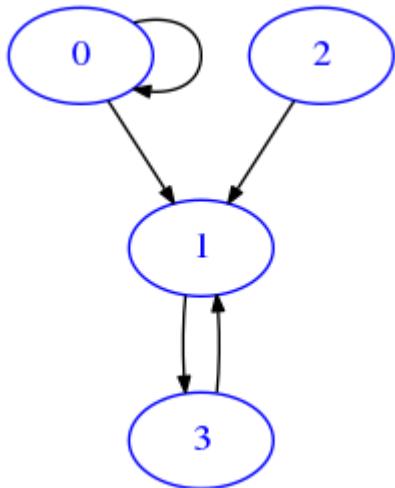

```
[9]: G2 = [
    [True, True, False, False],
    [False, False, False, True],
    [False, True, False, False],
```

(continues on next page)

(continued from previous page)

```
[False, True, False, False],  
]
```

[10]: draw_mat(G2)

```

A3 ediff

⊕⊕⊕ The *edge difference* of two graphs `ediff (da, db)` is a graph with the edges of the first except the edges of the second. For simplicity, here we consider only graphs having the same vertices but possibly different edges. This time we will try operate on graphs represented as dictionaries of adjacency lists.

For example, if we have

```
[12]: da = {
    'a': ['a', 'c'],
    'b': ['b', 'c'],
    'c': ['b', 'c']
}
```

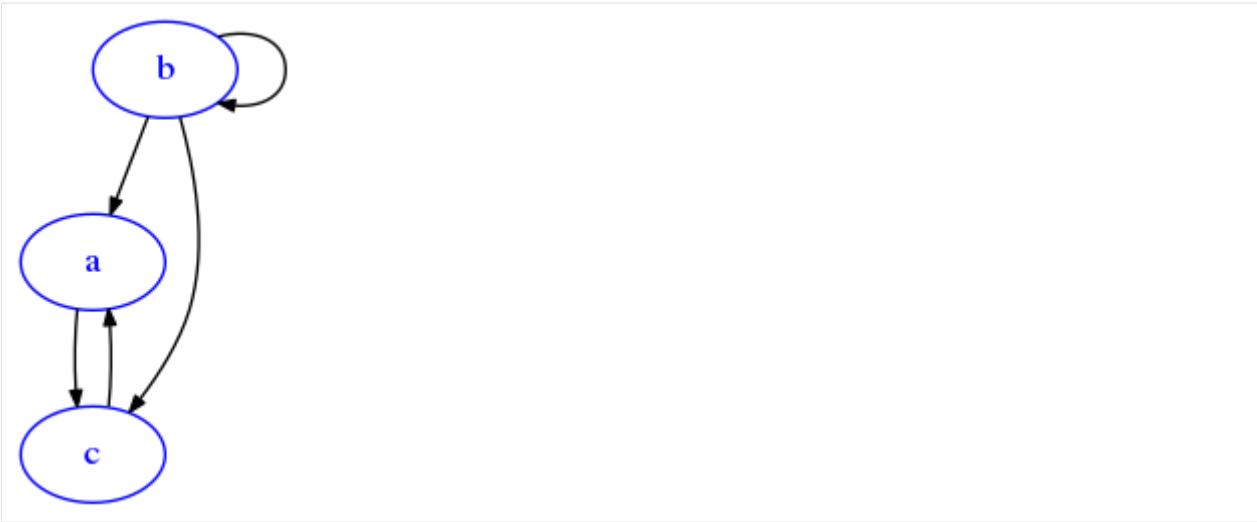

```
[13]: draw_adj(da)
```

and

```
[14]: db = {
    'a': ['c'],
    'b': ['a', 'b', 'c'],
    'c': ['a']
}
```

```
[15]: draw_adj(db)
```

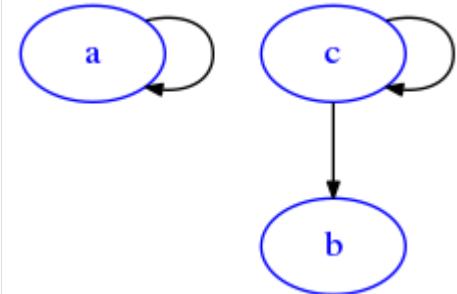

The result of calling `ediff(da, db)` will be:

```
[16]: res = {
        'a': ['a'],
        'b': [],
        'c': ['b', 'c']
    }
```

Which can be shown as

```
[17]: draw_adj(res)
```

Show solutionHide

```
[18]: def ediff(da, db):
    """ Takes two graphs as dictionaries of adjacency lists da and db, and
        RETURN a NEW graph as dictionary of adjacency lists, containing the same
        ↪vertices of da,
        and the edges of da except the edges of db.

        - As order of elements within the adjacency lists, use the same order as
        ↪found in da.
        - We assume all vertices in da and db are represented in the keys (even if
        ↪they have
        no outgoing edge), and that da and db have the same keys
```

EXAMPLE:

(continues on next page)

(continued from previous page)

```

```

2.1.3 Midterm - Thu 10, Jan 2019

Scientific Programming - Data Science Master @ University of Trento

[Download exercises and solution](#)

What to do

- 1) Download `sciprog-ds-2019-01-10-exam.zip` and extract it on your desktop. Folder content should be like this:

```

sciprog-ds-2019-01-10-FIRSTNAME-LASTNAME-ID
  gaps.py
  gaps_test.py
  tasks.py
  tasks_test.py
  exits.py
  exits_test.py

```

(continues on next page)

(continued from previous page)

```
jupman.py  
sciprog.py
```

- 2) Rename sciprog-ds-2019-01-10-FIRSTNAME-LASTNAME-ID folder: put your name, lastname and id number, like sciprog-ds-2019-01-10-john-doe-432432

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins.
If it takes longer, leave it and try another exercise.

- 4) When done:

if you have unitn login: zip and send to examina.icts.unitn.it⁶⁹

If you don't have unitn login: tell instructors and we will download your work manually

Introduction

B1 Theory

Please write the solution in the text file `theory.txt`

Given the following function:

```
def fun(N, M):  
    S1 = set(N)  
    S2 = set(M)  
    res = []  
    for x in S1:  
        if x in S2:  
            for i in range(N.count(x)):  
                res.append(x)  
    return res
```

let N and M be two lists of length n and m, respectively. What is the computational complexity of function `fun()` with respect to n and m?

B2 Gaps linked list

Given a linked list of size n which only contains integers, a gap is an index i , $0 < i < n$, such that $L[i-1] < L[i]$. For the purpose of this exercise, we assume an empty list or a list with one element have zero gaps

Example:

```
data:  9 7 6 8 9 2 2 5  
index: 0 1 2 3 4 5 6 7
```

contains three gaps [3,4,7] because:

- number 8 at index 3 is greater than previous number 6 at index 2
- number 9 at index 4 is greater than previous number 8 at index 3
- number 5 at index 7 is greater than previous number 2 at index 6

Open file `gaps.py` and implement this method:

⁶⁹ <http://examina.icts.unitn.it>

```
def gaps(self):
    """ Assuming all the data in the linked list is made by numbers,
    finds the gaps in the LinkedList and return them as a Python list.

    - we assume empty list and list of one element have zero gaps
    - MUST perform in O(n) where n is the length of the list

    NOTE: gaps to return are *indeces* , *not* data!!!!
    """

```

Testing: python3 -m unittest gaps_test.GapsTest

B3 Tasks stack

Very often, you begin to do a task just to discover it requires doing 3 other tasks, so you start carrying them out one at a time and discover one of them actually requires to do yet another two other subtasks....

To represent the fact a task may have subtasks, we will use a dictionary mapping a task label to a list of subtasks, each represented as a label. For example:

```
[2]: subtasks = {
    'a': ['b', 'g'],
    'b': ['c', 'd', 'e'],
    'c': ['f'],
    'd': ['g'],
    'e': [],
    'f': [],
    'g': []
}
```

Task a requires subtasks b and g to be carried out (in this order), but task b requires subtasks c, d and e to be done. c requires f to be done, and d requires g.

You will have to implement a function called `do` and use a Stack data structure, which is already provided and you don't need to implement. Let's see an example of execution.

IMPORTANT: In the execution example, there are many prints just to help you understand what's going on, but the only thing we actually care about is the final list returned by the function!

IMPORTANT: notice subtasks are scheduled in reversed order, so the item on top of the stack will be the first to get executed !

```
[3]: from tasks_sol import *

do('a', subtasks)

DEBUG: Stack: elements=['a']
DEBUG: Doing task a, scheduling subtasks ['b', 'g']
DEBUG:           Stack: elements=['g', 'b']
DEBUG: Doing task b, scheduling subtasks ['c', 'd', 'e']
DEBUG:           Stack: elements=['g', 'e', 'd', 'c']
DEBUG: Doing task c, scheduling subtasks ['f']
DEBUG:           Stack: elements=['g', 'e', 'd', 'f']
DEBUG: Doing task f, scheduling subtasks []
DEBUG:           Nothing else to do!
DEBUG:           Stack: elements=['g', 'e', 'd']
DEBUG: Doing task d, scheduling subtasks ['g']
```

(continues on next page)

(continued from previous page)

```
DEBUG:           Stack: elements=['g', 'e', 'g']
DEBUG: Doing task g, scheduling subtasks []
DEBUG:           Nothing else to do!
DEBUG:           Stack: elements=['g', 'e']
DEBUG: Doing task e, scheduling subtasks []
DEBUG:           Nothing else to do!
DEBUG:           Stack: elements=['g']
DEBUG: Doing task g, scheduling subtasks []
DEBUG:           Nothing else to do!
DEBUG:           Stack: elements=[]
```

[3]: ['a', 'b', 'c', 'f', 'd', 'g', 'e', 'g']

The Stack you must use is simple and supports push, pop, and is_empty operations:

[4]: s = Stack()

[5]: print(s)

```
Stack: elements=[]
```

[6]: s.is_empty()

[6]: True

[7]: s.push('a')

[8]: print(s)

```
Stack: elements=['a']
```

[9]: s.push('b')

[10]: print(s)

```
Stack: elements=['a', 'b']
```

[11]: s.pop()

[11]: 'b'

[12]: print(s)

```
Stack: elements=['a']
```

B3.1 do

Now open tasks_stack.py and implement function do:

```
def do(task, subtasks):
    """ Takes a task to perform and a dictionary of subtasks,
    and RETURN a list of performed tasks

    - To implement it, inside create a Stack instance and a while cycle.
```

(continues on next page)

(continued from previous page)

- DO *NOT* use a recursive function
 - Inside the function, you can use a print like "I'm doing task a', but that is only to help yourself in debugging, only the list returned by the function will be considered in the evaluation!
- """

Testing: python3 -m unittest tasks_test.DoTest

B3.2 do_level

In this exercise, you are asked to implement a slightly more complex version of the previous function where on the Stack you push two-valued tuples, containing the task label and the associated level. The first task has level 0, the immediate subtask has level 1, the subtask of the subtask has level 2 and so on and so forth. In the list returned by the function, you will put such tuples.

One possible use is to display the executed tasks as an indented tree, where the indentation is determined by the level. Here we see an example:

IMPORTANT: Again, the prints are only to let you understand what's going on, and you are *not* required to code them. The only thing that really matters is the list the function must return !

```
[13]: subtasks = {
    'a': ['b', 'g'],
    'b': ['c', 'd', 'e'],
    'c': ['f'],
    'd': ['g'],
    'e': [],
    'f': [],
    'g': []
}

do_level('a', subtasks)

DEBUG:                                     Stack:   elements=[('a', 0)]
DEBUG: I'm doing      a                 level=0 Stack:   elements=[('g', 1), ('b', 1)]
DEBUG: I'm doing      b                 level=1 Stack:   elements=[('g', 1), ('e', 2),
← ('d', 2), ('c', 2)]
DEBUG: I'm doing      c                 level=2 Stack:   elements=[('g', 1), ('e', 2),
← ('d', 2), ('f', 3)]
DEBUG: I'm doing      f                 level=3 Stack:   elements=[('g', 1), ('e', 2),
← ('d', 2)]
DEBUG: I'm doing      d                 level=2 Stack:   elements=[('g', 1), ('e', 2),
← ('g', 3)]
DEBUG: I'm doing      g                 level=3 Stack:   elements=[('g', 1), ('e', 2)]
DEBUG: I'm doing      e                 level=2 Stack:   elements=[('g', 1)]
DEBUG: I'm doing      g                 level=1 Stack:   elements=[]

[13]: [ ('a', 0),
        ('b', 1),
        ('c', 2),
        ('f', 3),
        ('d', 2),
        ('g', 3),
        ('e', 2),
        ('g', 1)]
```

Now implement the function:

```
def do_level(task, subtasks):
    """ Takes a task to perform and a dictionary of subtasks,
       and RETURN a list of performed tasks, as tuples (task label, level)

        - To implement it, use a Stack and a while cycle
        - DO *NOT* use a recursive function
        - Inside the function, you can use a print like "I'm doing task a",
          but that is only to help yourself in debugging, only the
          list returned by the function will be considered in the evaluation
    """

```

Testing: python3 -m unittest tasks_test.DoLevelTest

B4 Exits graph

There is a place nearby Trento called Silent Hill, where people always study and do little else. Unfortunately, one day an unethical biotech AI experiment goes wrong and a buggy cyborg is left free to roam in the building. To avoid panic, you are quickly asked to devise an evacuation plan. The place is a well known labyrinth, with endless corridors also looping into cycles. But you know you can model this network as a digraph, and decide to represent crossings as nodes. When a crossing has a door to leave the building, its label starts with letter e, while when there is no such door the label starts with letter n.

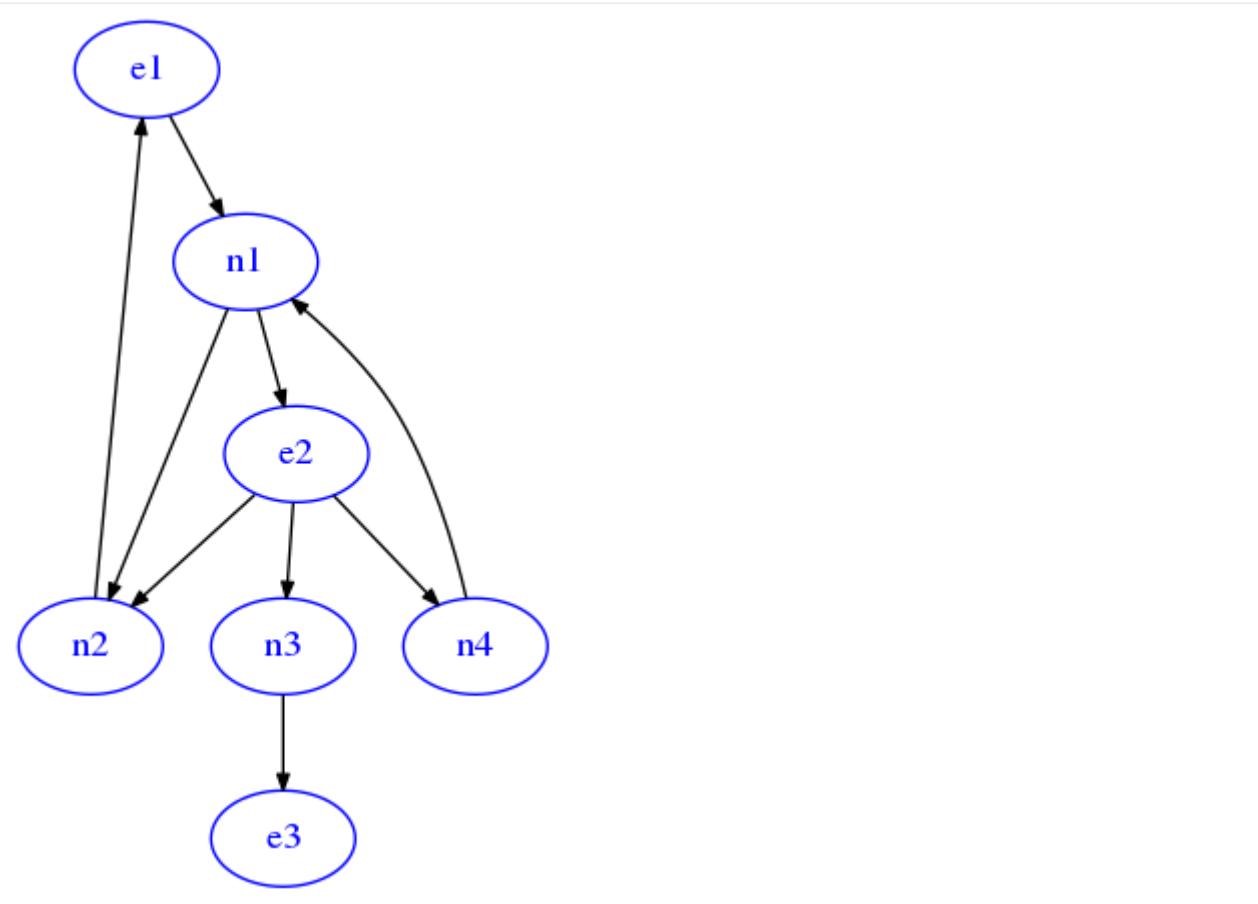

In the example below, there are three exits e1, e2, and e3. Given a node, say n1, you want to tell the crowd in that node the **shortest** paths leading to the three exits. To avoid congestion, one third of the crowd may be told to go to e2, one third to reach e1 and the remaining third will go to e3 even if they are farther than e2.

In python terms, we would like to obtain a dictionary of paths like the following, where as keys we have the exits and as values the shortest sequence of nodes from n1 leading to that exit

```
{
    'e1': ['n1', 'n2', 'e1'],
    'e2': ['n1', 'e2'],
    'e3': ['n1', 'e2', 'n3', 'e3']
}
```

```
[14]: from sciprog import draw_dig
from exits_sol import *
from exits_test import dig
```

```
[15]: G = dig({'n1':['n2','e2'],
              'n2':['e1'],
              'e1':['n1'],
              'e2':['n2','n3', 'n4'],
              'n3':['e3'],
              'n4':['n1']})
draw_dig(G)
```

You will solve the exercise in steps, so open `exits_sol.py` and proceed reading the following points.

B4.1 cp

Implement this method

```

def cp(self, source):
    """ Performs a BFS search starting from provided node label source and
    RETURN a dictionary of nodes representing the visit tree in the
    child-to-parent format, that is, each key is a node label and as value
    has the node label from which it was discovered for the first time

    So if node "n2" was discovered for the first time while
    inspecting the neighbors of "n1", then in the output dictionary there
    will be the pair "n2":"n1".

    The source node will have None as parent, so if source is "n1" in the
    output dictionary there will be the pair "n1": None

    NOTE: This method must *NOT* distinguish between exits
          and normal nodes, in the tests we label them n1, e1 etc just
          because we will reuse in next exercise
    NOTE: You are allowed to put debug prints, but the only thing that
          matters for the evaluation and tests to pass is the returned
  
```

(continues on next page)

(continued from previous page)

dictionary

....

Testing: python3 -m unittest exits_test.CpTest

Example:

[16]: G.cp('n1')

```
DEBUG: Removed from queue: n1
DEBUG: Found neighbor: n2
DEBUG: not yet visited, enqueueing ..
DEBUG: Found neighbor: e2
DEBUG: not yet visited, enqueueing ..
DEBUG: Queue is: ['n2', 'e2']
DEBUG: Removed from queue: n2
DEBUG: Found neighbor: e1
DEBUG: not yet visited, enqueueing ..
DEBUG: Queue is: ['e2', 'e1']
DEBUG: Removed from queue: e2
DEBUG: Found neighbor: n2
DEBUG: already visited
DEBUG: Found neighbor: n3
DEBUG: not yet visited, enqueueing ..
DEBUG: Found neighbor: n4
DEBUG: not yet visited, enqueueing ..
DEBUG: Queue is: ['e1', 'n3', 'n4']
DEBUG: Removed from queue: e1
DEBUG: Found neighbor: n1
DEBUG: already visited
DEBUG: Queue is: ['n3', 'n4']
DEBUG: Removed from queue: n3
DEBUG: Found neighbor: e3
DEBUG: not yet visited, enqueueing ..
DEBUG: Queue is: ['n4', 'e3']
DEBUG: Removed from queue: n4
DEBUG: Found neighbor: n1
DEBUG: already visited
DEBUG: Queue is: ['e3']
DEBUG: Removed from queue: e3
DEBUG: Queue is: []
```

[16]:

```
{'n1': None,
'n2': 'n1',
'e2': 'n1',
'e1': 'n2',
'n3': 'e2',
'n4': 'e2',
'e3': 'n3'}
```

Basically, the dictionary above represents this visit tree:

```
    n1
   /   \
  n2   e2
 /   \   \
e1   n3  n4
|
```

(continues on next page)

(continued from previous page)

e3

B4.2 exits

Implement this function. **NOTE:** the function is external to class DiGraph.

```
def exits(cp):
    """
        INPUT: a dictionary of nodes representing a visit tree in the
        child-to-parent format, that is, each key is a node label and as value
        has its parent as a node label. The root has associated None as parent.

        OUTPUT: a dictionary mapping node labels of exits to the shortest path
                from the root to the exit (root and exit included)

    """

```

Testing: python3 -m unittest exits_test.ExitsTest

Example:

```
[17]: # as example we can use the same dictionary outputted by the cp call in the previous
      ↪exercise

visit_cp = { 'e1': 'n2',
             'e2': 'n1',
             'e3': 'n3',
             'n1': None,
             'n2': 'n1',
             'n3': 'e2',
             'n4': 'e2'
         }
exits(visit_cp)
[17]: {'e1': ['n1', 'n2', 'e1'], 'e2': ['n1', 'e2'], 'e3': ['n1', 'e2', 'n3', 'e3']}
```

[]:

2.1.4 Exam - Wed 23, Jan 2019

Scientific Programming - Data Science Master @ University of Trento

Download exercises and solution

What to do

- 1) Download sciprog-ds-2019-01-23-exam.zip and extract it on your desktop. Folder content should be like this:

sciprog-ds-2019-01-23-FIRSTNAME-LASTNAME-ID exam-2019-01-23.ipynb

(continues on next page)

(continued from previous page)

```
list.py
list_test.py
tree.py
tree_test.py
jupman.py
sciprog.py
```

- 2) Rename sciprog-ds-2019-01-23-FIRSTNAME-LASTNAME-ID folder: put your name, lastname and id number, like sciprog-ds-2019-01-23-john-doe-432432

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins. If it takes longer, leave it and try another exercise.
- 4) When done:
 - if you have unitn login: zip and send to examina.icts.unitn.it/studente⁷⁰
 - If you don't have unitn login: tell instructors and we will download your work manually

Part A

Open Jupyter and start editing this notebook `exam-2019-01-23.ipynb`

A.1 table_to_adj

Suppose you have a table expressed as a list of lists with headers like this:

```
[2]: m0 = [
    ['Identifier', 'Price', 'Quantity'],
    ['a', 1, 1],
    ['b', 5, 8],
    ['c', 2, 6],
    ['d', 8, 5],
    ['e', 7, 3]
]
```

where `a`, `b`, `c` etc are the row identifiers (imagine they represent items in a store), `Price` and `Quantity` are properties they might have. **NOTE:** here we put two properties, but they might have n properties !

We want to transform such table into a graph-like format as a dictionary of lists, which relates store items as keys to the properties they might have. To include in the list both the property identifier and its value, we will use tuples. So you need to write a function that transforms the above input into this:

```
[3]: res0 = {
    'a': [('Price', 1), ('Quantity', 1)],
    'b': [('Price', 5), ('Quantity', 8)],
    'c': [('Price', 2), ('Quantity', 6)],
    'd': [('Price', 8), ('Quantity', 5)],
    'e': [('Price', 7), ('Quantity', 3)]
}
```

⁷⁰ <http://examina.icts.unitn.it/studente>

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

data-jupman-show="Show solution"

data-jupman-hide="Hide">Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[4]: def table_to_adj(table):

    ret = {}
    headers = table[0]

    for row in table[1:]:
        lst = []
        for j in range(1, len(row)):
            lst.append((headers[j], row[j]))
        ret[row[0]] = lst
    return ret

m0 = [
    ['I', 'P', 'Q']
]
res0 = {}

assert res0 == table_to_adj(m0)

m1 = [
    ['Identifier', 'Price', 'Quantity'],
    ['a', 1, 1],
    ['b', 5, 8],
    ['c', 2, 6],
    ['d', 8, 5],
    ['e', 7, 3]
]
res1 = {
    'a': [('Price', 1), ('Quantity', 1)],
    'b': [('Price', 5), ('Quantity', 8)],
    'c': [('Price', 2), ('Quantity', 6)],
    'd': [('Price', 8), ('Quantity', 5)],
    'e': [('Price', 7), ('Quantity', 3)]
}

assert res1 == table_to_adj(m1)

m2 = [
    ['I', 'P', 'Q'],
    ['a', 'x', 'y'],
    ['b', 'w', 'z'],

    'b':[('P','z'),('Q','x'), ('R','y')],
}
assert res3 == table_to_adj(m3)

```

A.2 bus stops

Today we will analzye intercity bus network in GTFS format taken from [dati.trentino.it⁷¹](https://dati.trentino.it/dataset/trasporti-pubblici-del-trentino-formato-gtfs), MITT service.

Original GTFS data was split in several files which we merged into dataset `data/network.csv` containing the bus stop times of three extra-urban routes. To load it, we provide this function:

```
[5]: def load_stops():
    "Loads file network.csv and RETURN a list of dictionaries with the stop times"

    import csv
    with open('data/network.csv', newline='', encoding='UTF-8') as csvfile:
        reader = csv.DictReader(csvfile)
        lst = []
        for d in reader:
            lst.append(d)
    return lst
```

```
[6]: stops = load_stops()

stops[0:2]

[6]: [OrderedDict([('1',
                    {'route_id': '76'},
                    {'agency_id': '12'},
                    {'route_short_name': 'B202'},
                    {'route_long_name',
                     'Trento-Sardagna-Candriai-Vaneze-Vason-Viote'},
                    {'route_type', '3'},
                    {'service_id', '22018091220190621'},
```

(continues on next page)

⁷¹ <https://dati.trentino.it/dataset/trasporti-pubblici-del-trentino-formato-gtfs>

(continued from previous page)

```
('trip_id', '0002402742018091220190621'),
('trip_headsign', 'Trento-Autostaz.'),
('direction_id', '0'),
('arrival_time', '06:25:00'),
('departure_time', '06:25:00'),
('stop_id', '844'),
('stop_sequence', '2'),
('stop_code', '2620'),
('stop_name', 'Sardagna'),
('stop_desc', ''),
('stop_lat', '46.064848'),
('stop_lon', '11.09729'),
('zone_id', '2620.0'))],
OrderedDict([("'", '2'),
    ('route_id', '76'),
    ('agency_id', '12'),
    ('route_short_name', 'B202'),
    ('route_long_name',
        'Trento-Sardagna-Candriai-Vaneze-Vason-Viote'),
    ('route_type', '3'),
    ('service_id', '22018091220190621'),
    ('trip_id', '0002402742018091220190621'),
    ('trip_headsign', 'Trento-Autostaz.'),
    ('direction_id', '0'),
    ('arrival_time', '06:26:00'),
    ('departure_time', '06:26:00'),
    ('stop_id', '5203'),
    ('stop_sequence', '3'),
    ('stop_code', '2620VD'),
    ('stop_name', 'Sardagna Civ. 22'),
    ('stop_desc', ''),
    ('stop_lat', '46.069494'),
    ('stop_lon', '11.095252'),
    ('zone_id', '2620.0')])]
```

Of interest to you are the fields `route_short_name`, `arrival_time`, and `stop_lat` and `stop_lon` which provide the geographical coordinates of the stop. Stops are already sorted in the file from earliest to latest.

Given a `route_short_name`, like B202, we want to plot the graph of bus velocity measured in **km/hours** at each stop. We define velocity at stop n as

$$\text{velocity}_n = \frac{\Delta \text{space}_n}{\Delta \text{time}_n}$$

where

$\Delta \text{time}_n = \text{time}_n - \text{time}_{n-1}$ as the time **in hours** the bus takes between stop n and stop $n - 1$.

and

$\Delta \text{space}_n = \text{space}_n - \text{space}_{n-1}$ is the distance the bus has moved between stop n and stop $n - 1$.

We also set $\text{velocity}_0 = 0$

NOTE FOR TIME: When we say time in **hours**, it means that if you have the time as string `08:27:42`, its number in seconds since midnight is like:

```
[7]: secs = 8*60*60+27*60+42
```

and to calculate the time in **float hours** you need to divide `secs` by $60*60=3600$:

```
[8]: hours_float = secs / (60*60)
hours_float
[8]: 8.461666666666666
```

NOTE FOR SPACE: Unfortunately, we could not find the actual distance as road length done by the bus between one stop and the next one. So, for the sake of the exercise, we will take the *geo distance*, that is, we will calculate it using the line distance between the points of the stops, using their geographical coordinates. The function to calculate the geo_distance is already implemented :

```
[9]: def geo_distance(lat1, lon1, lat2, lon2):
    """ Return the geo distance in kilometers
    between the points 1 and 2 at provided geographical coordinates.

    """
    # Shamelessly copied from https://stackoverflow.com/a/19412565

    from math import sin, cos, sqrt, atan2, radians

    # approximate radius of earth in km
    R = 6373.0

    lat1 = radians(lat1)
    lon1 = radians(lon1)
    lat2 = radians(lat2)
    lon2 = radians(lon2)

    dlon = lon2 - lon1
    dlat = lat2 - lat1

    a = sin(dlat / 2)**2 + cos(lat1) * cos(lat2) * sin(dlon / 2)**2
    c = 2 * atan2(sqrt(a), sqrt(1 - a))

    return R * c
```

In the following we see the bus line B102, going from Sardagna to Trento. The graph should show something like the following.

We can see that as long as the bus is taking stops within Sardagna town, velocity (always intended as air-line velocity) is high, but when the bus has to go to Trento, since there are many twists and turns on the road, it takes a while to arrive even if in geo-distance Trento is near, so actual velocity decreases. In such case it would be much more convenient to take the cable car.

These type of graphs might show places in the territory where shortcuts such as cable cars, tunnels or bridges might be helpful for transportation.

<a class="jupman-sol" jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

Show solution<div class="jupman-sol" jupman-sol-code" style="display:none">

```
[10]: def to_float_hour(time_string):
    """
    Takes a time string in the format like 08:27:42
    and RETURN the time since midnight in hours as a float (es 8.461666666666666)
    """

    hours = int(time_string[0:2])

```

Part B

B.1 Theory

Let L a list of size n , and i and j two indeces. Return the computational complexity of function `fun()` with respect to n .

```
def fun(L, i, j):
    if i==j:
        return 0
    else:
        m = (i+j)//2
        count = 0
        for x in L[i:m]:
            for y in L[m:j+1]:
                if x==y:
                    count = count+1
        left = fun(L, i, m)
        right = fun(L, m+1, j)
        return left+right+count
```

Show answer<div class="jupman-sol jupman-sol-question" style="display:none">

ANSWER: write solution here

$O(n^2)$

</div>

B.2 Linked List flatv

Suppose a `LinkedList` only contains integer numbers, say 3,8,8,7,5,8,6,3,9. Implement method `flatv` which scans the list: when it finds the *first* occurrence of a node which contains a number which is less than the previous one, and the less than successive one, it inserts after the current one another node with the same data as the current one, and exits.

Example:

for Linked list 3,8,8,7,5,8,6,3,9

calling `flatv` should modify the linked list so that it becomes

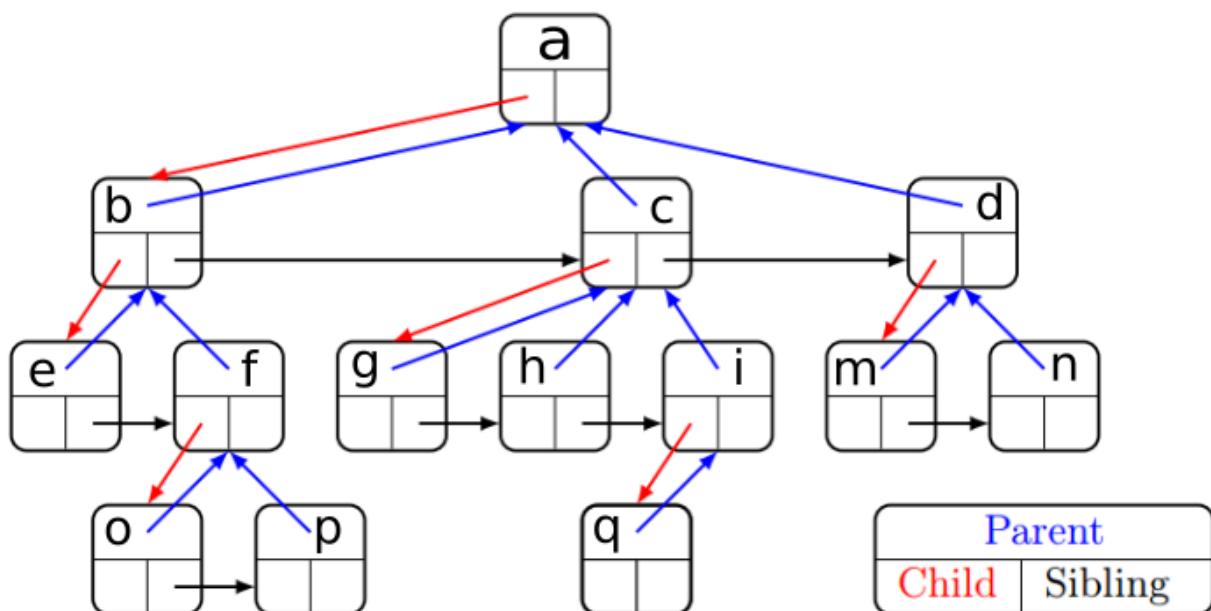

Linked list 3,8,8,7,5,5,8,6,3,9

Note that it only modifies the first occurrence found 7,5,8 to 7,5,5,8 and the successive sequence 6,3,9 is not altered

Open `list.py` and implement this method:

```
def flatv(self):
```

B.3 Generic Tree rightmost

In the example above, the rightmost branch of a is given by the node sequence a,d,n

Open `tree.py` and implement this method:

```
def rightmost(self):
    """ RETURN a list containing the *data* of the nodes
    in the *rightmost* branch of the tree.

    Example:
        a
        ↗b
        ↗c
        ↗d
        ↗e
        ↗f
        ↗g
        ↗h
        ↗i
        ↗j
        ↗k
        ↗l
        ↗m
        ↗n
        ↗o
        ↗p
        ↗q
        ↗r
        ↗s
        ↗t
        ↗u
        ↗v
        ↗w
        ↗x
        ↗y
        ↗z
    """
    pass
```

(continues on next page)

(continued from previous page)

```
②c  
②e  
②d  
②f  
②g  
②h  
②i
```

should give

```
["a", "d", "g", "i"]  
"""
```

2.1.5 Exam - Wed 13, Feb 2019

Scientific Programming - Data Science @ University of Trento

Download exercises and solution

Introduction

- Taking part to this exam erases any vote you had before

What to do

- 1) Download `sciprog-ds-2019-02-13-exam.zip` and extract it on your desktop. Folder content should be like this:

```
sciprog-ds-2019-02-13-FIRSTNAME-LASTNAME-ID  
exam-2019-02-13.ipynb  
company.py  
company_test.py  
tree.py  
tree_test.py  
jupman.py  
sciprog.py
```

- 2) Rename `sciprog-ds-2019-02-13-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2019-02-13-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins.
If it takes longer, leave it and try another exercise.
- 4) When done:
 - if you have unitn login: zip and send to examina.icts.unitn.it/studente⁷²
 - If you don't have unitn login: tell instructors and we will download your work manually

⁷² <http://examina.icts.unitn.it/studente>

Part A - Bus network visualization

Open Jupyter and start editing this notebook exam-2019-02-13.ipynb

Today we will visualize intercity bus network in GTFS format taken from dati.trentino.it⁷³, MITT service. Original data was split in several files which we merged into dataset [data/network-short.csv](#).

To visualize it, we will use [networkx](#)⁷⁴ library. Let's first see an example on how to do it:

```
[2]: import networkx as nx
from sciprog import draw_nx

Gex = nx.DiGraph()

# we can force horizontal layout like this:

Gex.graph['graph'] = {
    'rankdir': 'LR',
}

# When we add nodes, we can identify them with an identifier like the
# stop_id which is separate from the label, because in some unfortunate
# case two different stops can share the same label.

Gex.add_node('1', label='Trento-Autostaz.',
             color='black', fontcolor='black')
Gex.add_node('723', label='Trento-Via Brescia 4',
             color='black', fontcolor='black')
Gex.add_node('870', label='Sarch Centro comm.',
             color='black', fontcolor='black')
Gex.add_node('1180', label='Trento Corso 3 Novembre',
             color='black', fontcolor='black')

# IMPORTANT: edges connect stop_ids , NOT labels !!!!
Gex.add_edge('870', '1')
Gex.add_edge('723', '1')
Gex.add_edge('1', '1180')

# function defined in sciprog.py :
draw_nx(Gex)
```

⁷³ <https://dati.trentino.it/dataset/trasporti-pubblici-del-trentino-formato-gtfs>

⁷⁴ <https://networkx.github.io/>

Colors and additional attributes

Since we have a bus stop netowrk, we might want to draw edges according to the route they represent. Here we show how to do it only with the edge from *Trento-Autostaz* to *Trento Corso 3 Novembre*:

```
[3]: # we can retrieve an edge like this:

edge = Gex['1']['1180']

# and set attributes, like these:

edge['weight'] = 5          # it takes 5 minutes to go from Trento-Autostaz
                           # to Trento Corso 3 Novembre
edge['label'] = str(5)       # the label is a string

edge['color'] = '#2ca02c'     # we can set some style for the edge, such as color
edge['penwidth']= 4           # and thickness

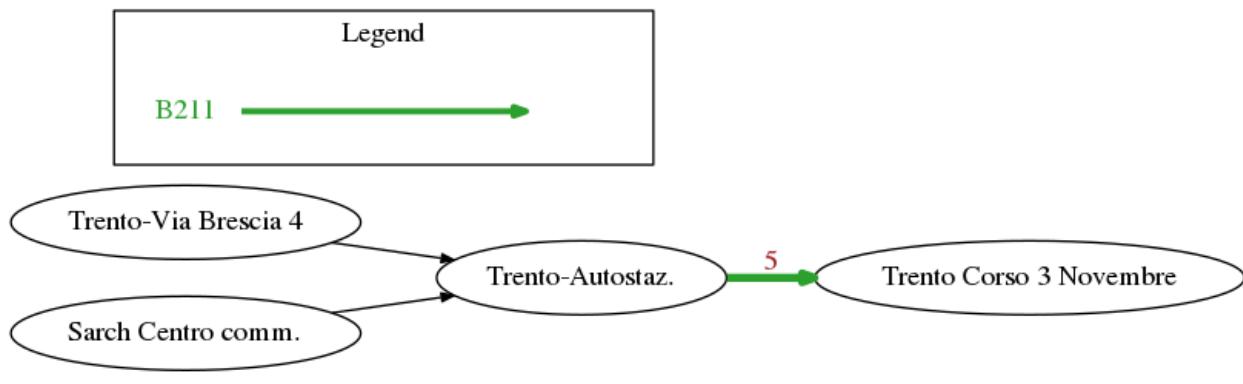

edge['route_short_name'] = 'B301' # we can add any attribute we want,
                                # Note these custom ones won't show in the graph

draw_nx(Gex)
```

To be more explicit, we can also add a legend this way:

```
[4]: draw_nx(Gex, [{'color': '#2ca02c', 'label': 'B211'}])
```

```
[5]: # Note an edge is a simple dictionary:
print(edge)
```

```
{'color': '#2ca02c', 'penwidth': 4, 'weight': 5, 'label': '5', 'route_short_name':
↪'B301'}
```

load_stops

To load `network-short.csv`, we provide this function:

```
[6]: def load_stops():
    """Loads file data and RETURN a list of dictionaries with the stop times
    """

    import csv
    with open('data/network-short.csv', newline='', encoding='UTF-8') as csvfile:
        reader = csv.DictReader(csvfile)
        lst = []
        for d in reader:
            lst.append(d)
    return lst
```

```
[7]: stops = load_stops()
```

*#IMPORTANT: NOTICE *ALL* VALUES ARE *STRINGS* !!!!!!!*

```
stops[0:2]
```

```
[7]: [{': '3',
  'agency_id': '12',
  'arrival_time': '06:27:00',
  'departure_time': '06:27:00',
  'direction_id': '0',
  'route_id': '76',
  'route_long_name': 'Trento-Sardagna-Candriai-Vaneze-Vason-Viote',
  'route_short_name': 'B202',
  'route_type': '3',
  'service_id': '22018091220190621',
  'stop_code': '2620VE',
  'stop_desc': '',
  'stop_id': '5025',
  'stop_lat': '46.073125',
  'stop_lon': '11.093579',
  'stop_name': 'Sardagna Civ.20',
  'stop_sequence': '4',
  'trip_headsign': 'Trento-Autostaz.',
  'trip_id': '0002402742018091220190621',
  'zone_id': '2620.0'},
 {': '4',
  'agency_id': '12',
  'arrival_time': '06:28:00',
  'departure_time': '06:28:00',

  'stop_code': '2620MS',
  'stop_desc': '',
  'stop_id': '843',
  'stop_lat': '46.069871',
  'stop_lon': '11.097749',
```

(continues on next page)

(continued from previous page)

```
'stop_name': 'Sardagna-Maso Scala',
'stop_sequence': '5',
'trip_headsign': 'Trento-Autostaz.',
'trip_id': '0002402742018091220190621',
'zone_id': '2620.0'}]
```

A1 extract_routes

Implement extract_routes function:

```
<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"
    data-jupman-show="Show solution"
    data-jupman-hide="Hide">Show solution</a><div class="jupman-sol jupman-sol-code" style="display:none">
```

[8]:

```
import networkx as nx
from sciprog import draw_nx

stops = load_stops()

def extract_routes(stops):
    """ Extract all route_short_name from the stops list and RETURN
        an alphabetically sorted list of them, without duplicates
        (see example)

    """
    s = set()
    for diz in stops:
        s.add(diz['route_short_name'])
    ret = list(s)
    ret.sort()
    return ret
```

</div>

[8]:

```
import networkx as nx
from sciprog import draw_nx

stops = load_stops()

def extract_routes(stops):
    """ Extract all route_short_name from the stops list and RETURN
        an alphabetically sorted list of them, without duplicates
        (see example)

    """
    raise Exception('TODO IMPLEMENT ME !')
```

Example:

[9]: extract_routes(stops)

[9]: ['B201', 'B202', 'B211', 'B217', 'B301']

A2 to_int_min

Implement this function:

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

data-jupman-show="Show solution"

data-jupman-hide="Hide">Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

[10]:

```
def to_int_min(time_string):
    """
        Takes a time string in the format like 08:27:42
        and RETURN the time since midnight in minutes, ignoring
        the seconds (es 507)
    """

    hours = int(time_string[0:2])
    mins = int(time_string[3:5])
    return (hours * 60 + mins)
```

</div>

[10]:

```
def to_int_min(time_string):
    """
        Takes a time string in the format like 08:27:42
        and RETURN the time since midnight in minutes, ignoring
        the seconds (es 507)
    """

    raise Exception('TODO IMPLEMENT ME !')
```

Example:

[11]: to_int_min('08:27:42')

[11]: 507

A3 get_legend_edges

If you have n routes numbered from 0 to $n-1$, and you want to assign to each of them a different color, we provide this function:

```
def get_color(i, n):
    """
        RETURN the i-th color chosen from n possible colors, in
        hex format (i.e. #ff0018).

        - if i < 0 or i >= n, raise ValueError
    """

    if n < 1:
        raise ValueError("Invalid n: %s" % n)
    if i < 0 or i >= n:
        raise ValueError("Invalid i: %s" % i)

    #HACKY, just for matplotlib < 3
    lst = ['#1f77b4',
           '#ff7f0e',
           '#2ca02c',
```

(continues on next page)

(continued from previous page)

```
'#d62728',
'#9467bd',
'#8c564b',
'#e377c2',
'#7f7f7f',
'#bcbd22',
'#17becf']

return lst[i % 10]
```

[13]: get_color(4,5)

[13]: '#9467bd'

Now implement this function:

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

data-jupman-show="Show solution"

data-jupman-hide="Hide">Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[14]: def get_legend_edges():
    """
        RETURN a list of dictionaries, where each dictionary represent a route
        with label and associated color. Dictionaries are in the order returned by
        extract_routes() function.
    """

    legend_edges = []
    i = 0
    routes = extract_routes(stops)

    for route_short_name in routes:
        legend_edges.append({
            'label': route_short_name,
            'color':get_color(i,len(routes))
        })
        i += 1
    return legend_edges
```

</div>

```
[14]: def get_legend_edges():
    """
        RETURN a list of dictionaries, where each dictionary represent a route
        with label and associated color. Dictionaries are in the order returned by
        extract_routes() function.
    """

    """
    raise Exception('TODO IMPLEMENT ME !')

```

```
[17]: G = calc_nx(stops)

draw_nx(G, get_legend_edges())
```

A5 color_hubs

A *hub* is a node that allows to switch route, that is, it is touched by *at least* two different routes.

For example, *Trento-Autostaz* is touched by three routes, which is more than one, so it is a hub. Let's examine the node - we know it has `stop_id='1'`:

```
[18]: G.node['1']
[18]: {'color': 'black', 'fontcolor': 'black', 'label': 'Trento\nAutostaz.'}
```

If we examine its `in_edges`, we find it has incoming edges from `stop_id '723'` and `'870'`, which represent respectively *Trento Via Brescia* and *Sarche Centro Commerciale*:

```
[19]: G.in_edges('1')
[19]: InEdgeDataView([('723', '1'), ('870', '1')])
```

If you get a `View` object, if needed you can easily transform to a list:

```
[20]: list(G.in_edges('1'))
[20]: [('723', '1'), ('870', '1')]

[21]: G.node['723']
[21]: {'color': 'black', 'fontcolor': 'black', 'label': 'Trento\nVia\nBrescia\nn4'}

[22]: G.node['870']
[22]: {'color': 'black', 'fontcolor': 'black', 'label': 'Sarche\nCentro\nnComm.'}
```

There is only an outgoing edge toward *Trento Corso 3 Novembre*:

```
[23]: G.out_edges('1')
```

```
[23]: OutEdgeDataView([('1', '1108')])
```

```
[24]: G.node['1108']
```

```
[24]: {'color': 'black',
       'fontcolor': 'black',
       'label': 'Trento\nC.So\nTre\nNovembre'}
```

If, for example, we want to know the `route_id` of this outgoing edge, we can access it this way:

```
[25]: G['1']['1108']
```

```
[25]: {'color': '#9467bd',
       'label': '5',
       'penwidth': 4,
       'route_short_name': 'B301',
       'weight': 5}
```

If you want to change the color attribute of the node '1', you can write like this:

```
[26]: G.node['1']['color'] = 'red'
G.node['1']['fontcolor'] = 'red'
```

Now implement the function `color_hubs`:

```
<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"
data-jupman-show="Show solution"
data-jupman-hide="Hide">Show solution</a><div class="jupman-sol jupman-sol-code" style="display:none">
```

```
[27]: def color_hubs(G):
    """ Print the hubs in the graph G as text, and then draws the graph
    with the hubs colored in red.

    NOTE: you don't need to recalculate the graph, just set the relevant
    nodes color to red

    """

    G.name = '***** color_hubs SOLUTION '

    hubs = []
    for node in G.nodes():
        edges = list(G.in_edges(node)) + list(G.out_edges(node))
        route_short_names = set()
        for edge in edges:
            route_short_names.add(G[edge[0]][edge[1]]['route_short_name'])
        if len(route_short_names) > 1:
            hubs.append(node)

    print("SOLUTION: The hubs are:")
    print()

    for hub in hubs:
        print("stop_id:%s\n%s\n" % (hub, G.node[hub]['label']))
        G.node[hub]['color'] = 'red'
        G.node[hub]['fontcolor'] = 'red'
```

(continues on next page)

(continued from previous page)

```
draw_nx(G, legend_edges=get_legend_edges())
```

</div>

```
[27]: def color_hubs(G):
    """ Print the hubs in the graph G as text, and then draws the graph
    with the hubs colored in red.

    NOTE: you don't need to recalculate the graph, just set the relevant
    nodes color to red

    """
    raise Exception('TODO IMPLEMENT ME !')
    draw_nx(G, legend_edges=get_legend_edges())
```

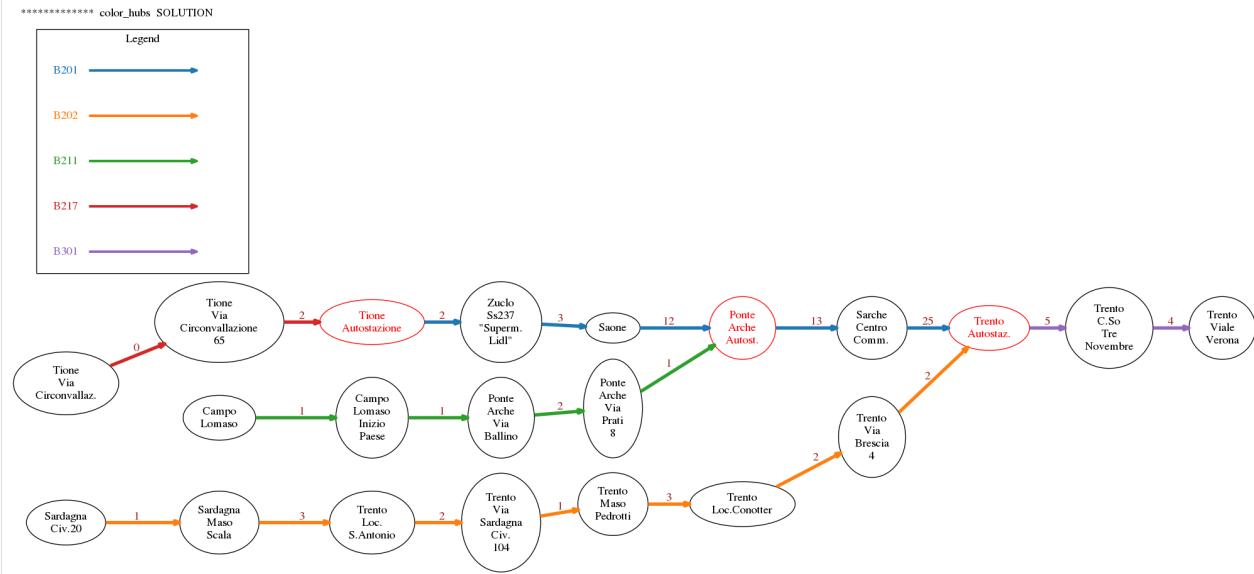

```
[28]: color_hubs(G)
```

SOLUTION: The hubs are:

stop_id:757
Tione
Autostazione

stop_id:742
Ponte
Arche
Autost.

stop_id:1
Trento
Autostaz.

A6 plot_timings

To extract bus times from G, use this:

```
[29]: G.edges()  
[29]: OutEdgeView([('842', '3974'), ('757', '746'), ('829', '3213'), ('1556', '4392'), ('3974', '841'), ('4391', '4390'), ('857', '742'), ('4392', '4391'), ('5025', '843'), ('841', '881'), ('723', '1'), ('742', '870'), ('870', '1'), ('3213', '757'), ('1', '1108'), ('843', '842'), ('746', '857'), ('1108', '1109'), ('881', '723'), ('4390', '742')])
```

If you get a View, you can iterate through the sequence like it were a list

To get the data from an edge, you can use this:

```
[30]: G.get_edge_data('1', '1108')  
[30]: {'color': '#9467bd',  
       'label': '5',  
       'penwidth': 4,  
       'route_short_name': 'B301',  
       'weight': 5}
```

Now implement the function `plot_timings`:

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"
data-jupman-show="Show solution"
data-jupman-hide="Hide">Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[31]: def plot_timings(G):  
    """  
        Given a networkx DiGraph G plots a frequency histogram of the  
        time between bus stops.  
    """  
  
    import numpy as np  
    import matplotlib.pyplot as plt  
  
    timings = [G.get_edge_data(edge[0], edge[1])['weight'] for edge in G.edges()]  
  
    import matplotlib.pyplot as plt  
    import numpy as np  
  
    # add histogram  
  
    min_x = min(timings)  
    max_x = max(timings)  
    bar_width = 1.0  
  
    # in this case hist returns a tuple of three values  
    # we put in three variables  
    n, bins, columns = plt.hist(timings,  
                                bins=range(min_x, max_x + 1),  
                                width=1.0)           # graphical width of the bars  
  
    xs = np.arange(min_x, max_x + 1)
```

(continues on next page)

(continued from previous page)

```

plt.xlabel('Time between stops in minutes')
plt.ylabel('Frequency counts')
plt.title('Time histogram SOLUTION')
plt.xlim(0, max(timings) + 2)
plt.xticks(xs + bar_width / 2, # position of ticks
          xs)
plt.show()

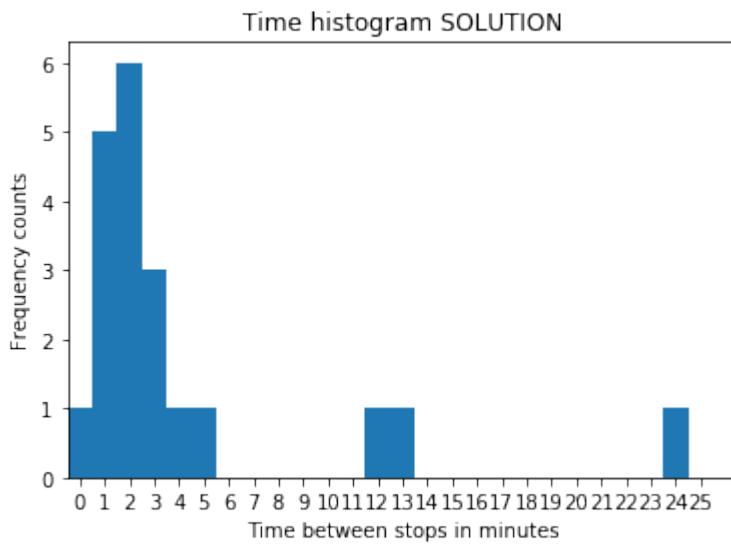

```

</div>

```
[31]: def plot_timings(G):
    """
        Given a networkx DiGraph G plots a frequency histogram of the
        time between bus stops.

    """
    raise Exception('TODO IMPLEMENT ME !')
```

```
[32]: plot_timings(G)
```

Part B

B.1 Theory

Let L a list of size n , and i and j two indeces. Return the computational complexity of function `fun()` with respect to n .

Write the solution in separate ``theory.txt`` file

```

def fun(L, i, j):
    # j-i+1 is the number of elements
    # between index i and index j (both included)
    if j-i+1 <= 3:
```

(continues on next page)

(continued from previous page)

```
# Compute their minimum
    return min(L[i:j+1])
else:
    onethird = (j-i+1)//3
    res1 = fun(L,i, i+onethird)
    res2 = fun(L,i+onethird+1, i+2*onethird)
    res3 = fun(L,i+2*onethird+1, j)
    return min(res1,res2,res3)
```

Show answer<div class="jupman-sol jupman-sol-question" style="display:none">

ANSWER: $\Theta(n)$

</div>

B2 Company queues

We can model a company as a list of many employees ordered by their rank, the highest ranking being the first in the list. We assume all employees have different rank. Each employee has a name, a rank, and a queue of tasks to perform (as a Python deque).

When a new employee arrives, it is inserted in the list in the right position according to his rank:

```
[33]: from company_sol import *
c = Company()
print(c)
```

```
Company:
  name  rank  tasks
```

```
[34]: c.add_employee('x', 9)
```

```
[35]: print(c)
```

```
Company:
  name  rank  tasks
  x      9      deque([])
```

```
[36]: c.add_employee('z', 2)
```

```
[37]: print(c)
```

```
Company:
  name  rank  tasks
  x      9      deque([])
  z      2      deque([])
```

```
[38]: c.add_employee('y', 6)
```

```
[39]: print(c)
```

```
Company:
  name  rank  tasks
  x      9      deque([])
  y      6      deque([])
  z      2      deque([])
```

B2.1 add_employee

Implement this method:

```
def add_employee(self, name, rank):
    """
        Adds employee with name and rank to the company, maintaining
        the _employees list sorted by rank (higher rank comes first)

        Represent the employee as a dictionary with keys 'name', 'rank'
        and 'tasks' (a Python deque)

        - here we don't mind about complexity, feel free to use a
          linear scan and .insert
        - If an employee of the same rank already exists, raise ValueError
        - if an employee of the same name already exists, raise ValueError
    """
```

Testing: python3 -m unittest company_test.AddEmployeeTest

B2.2 add_task

Each employee has a queue of tasks to perform. Tasks enter from the right and leave from the left. Each task has associated a required rank to perform it, but when it is assigned to an employee the required rank may exceed the employee rank or be far below the employee rank. Still, when the company receives the task, it is scheduled in the given employee queue, ignoring the task rank.

```
[40]: c.add_task('a', 3, 'x')
```

```
[41]: c
```

```
[41]: Company:
  name  rank  tasks
  x      9      deque([('a', 3)])
  y      6      deque([])
  z      2      deque([])
```

```
[42]: c.add_task('b', 5, 'x')
```

```
[43]: c
```

```
[43]:
```

```
Company:  
  name  rank  tasks  
  x      9      deque([('a', 3), ('b', 5)])  
  y      6      deque([])  
  z      2      deque([])
```

```
[44]: c.add_task('c', 12, 'x')  
c.add_task('d', 1, 'x')  
c.add_task('e', 8, 'y')  
c.add_task('f', 2, 'y')  
c.add_task('g', 8, 'y')  
c.add_task('h', 10, 'z')
```

```
[45]: c
```

```
[45]:
```

```
Company:  
  name  rank  tasks  
  x      9      deque([('a', 3), ('b', 5), ('c', 12), ('d', 1)])  
  y      6      deque([('e', 8), ('f', 2), ('g', 8)])  
  z      2      deque([('h', 10)])
```

Implement this function:

```
def add_task(self, task_name, task_rank, employee_name):  
    """ Append the task as a (name, rank) tuple to the tasks of  
    given employee  
  
        - If employee does not exist, raise ValueError  
    """
```

Testing: python3 -m unittest company_test.AddTaskTest

B2.2 work

Work in the company is produced in work steps. Each work step produces a list of all task names executed by the company in that work step.

A work step is done this way:

For each employee, starting from the highest ranking one, dequeue its current task (from the left), and then compare the task required rank with the employee rank according to these rules:

- When an employee discovers a task requires a rank strictly greater than his rank, he will append the task to his supervisor tasks. Note the highest ranking employee may be forced to do tasks that are greater than his rank.
- When an employee discovers he should do a task requiring a rank strictly less than his, he will try to see if the next lower ranking employee can do the task, and if so append the task to that employee tasks.
- When an employee cannot pass the task to the supervisor nor the next lower ranking employee, he will actually execute the task, adding it to the work step list

Example:

[46]: c

[46]:

```
Company:
  name  rank  tasks
  x      9     deque([('a', 3), ('b', 5), ('c', 12), ('d', 1)])
  y      6     deque([('e', 8), ('f', 2), ('g', 8)])
  z      2     deque([('h', 10)])
```

[47]: c.work()

```
DEBUG: Employee x gives task ('a', 3) to employee y
DEBUG: Employee y gives task ('e', 8) to employee x
DEBUG: Employee z gives task ('h', 10) to employee y
DEBUG: Total performed work this step: []
```

[47]: []

[48]: c

[48]:

```
Company:
  name  rank  tasks
  x      9     deque([('b', 5), ('c', 12), ('d', 1), ('e', 8)])
  y      6     deque([('f', 2), ('g', 8), ('a', 3), ('h', 10)])
  z      2     deque([])
```

[49]: c.work()

```
DEBUG: Employee x gives task ('b', 5) to employee y
DEBUG: Employee y gives task ('f', 2) to employee z
DEBUG: Employee z executes task ('f', 2)
DEBUG: Total performed work this step: ['f']
```

[49]: ['f']

[50]: c

[50]:

```
Company:
  name  rank  tasks
  x      9     deque([('c', 12), ('d', 1), ('e', 8)])
  y      6     deque([('g', 8), ('a', 3), ('h', 10), ('b', 5)])
  z      2     deque([])
```

[51]: c.work()

```
DEBUG: Employee x executes task ('c', 12)
DEBUG: Employee y gives task ('g', 8) to employee x
DEBUG: Total performed work this step: ['c']
```

[51]: ['c']

[52]: c

[52]:

```
Company:
  name  rank  tasks
  x      9     deque([('d', 1), ('e', 8), ('g', 8)])
```

(continues on next page)

(continued from previous page)

```
y      6    deque([('a', 3), ('h', 10), ('b', 5)])
z      2    deque([])
```

[53]: c.work()

```
DEBUG: Employee x gives task ('d', 1) to employee y
DEBUG: Employee y executes task ('a', 3)
DEBUG: Total performed work this step: ['a']
```

[53]: ['a']

[54]: c

[54]:

```
Company:
  name  rank  tasks
  x      9    deque([('e', 8), ('g', 8)])
  y      6    deque([('h', 10), ('b', 5), ('d', 1)])
  z      2    deque([])
```

[55]: c.work()

```
DEBUG: Employee x executes task ('e', 8)
DEBUG: Employee y gives task ('h', 10) to employee x
DEBUG: Total performed work this step: ['e']
```

[55]: ['e']

[56]: c

[56]:

```
Company:
  name  rank  tasks
  x      9    deque([('g', 8), ('h', 10)])
  y      6    deque([('b', 5), ('d', 1)])
  z      2    deque([])
```

[57]: c.work()

```
DEBUG: Employee x executes task ('g', 8)
DEBUG: Employee y executes task ('b', 5)
DEBUG: Total performed work this step: ['g', 'b']
```

[57]: ['g', 'b']

[58]: c

[58]:

```
Company:
  name  rank  tasks
  x      9    deque([('h', 10)])
  y      6    deque([('d', 1)])
  z      2    deque([])
```

[59]: c.work()

```
DEBUG: Employee x executes task ('h', 10)
DEBUG: Employee y gives task ('d', 1) to employee z
```

(continues on next page)

(continued from previous page)

```
DEBUG: Employee z executes task ('d', 1)
DEBUG: Total performed work this step: ['h', 'd']
[59]: ['h', 'd']
```

```
[60]: c
```

```
[60]: Company:
      name  rank  tasks
      x      9    deque([])
      y      6    deque([])
      z      2    deque([])
```

Now implement this method:

```
def work(self):
    """ Performs a work step and RETURN a list of performed task names.

    For each employee, dequeue its current task from the left and:
    - if the task rank is greater than the rank of the
      current employee, append the task to his supervisor queue
      (the highest ranking employee must execute the task)
    - if the task rank is lower or equal to the rank of the
      next lower ranking employee, append the task to that employee
      queue
    - otherwise, add the task name to the list of
      performed tasks to return
    """

```

Testing: python3 -m unittest company_test.WorkTest

B3 GenericTree

B3.1 fill_left

Open tree.py and implement fill_left method:

```
def fill_left(self, stuff):
    """ MODIFIES the tree by filling the leftmost branch data
    with values from provided array 'stuff'

    - if there aren't enough nodes to fill, raise ValueError
    - root data is not modified
    - *DO NOT* use recursion

    """

```

Testing: python3 -m unittest tree_test.FillLeftTest

Example:

```
[61]: from tree_test import gt
from tree_sol import *
```

```
[62]: t = gt('a',
             gt('b',
                 gt('e',
                     gt('f'),
                     gt('g',
                         gt('i'))),
                 gt('h')),
             gt('c'),
             gt('d')))
```

```
[63]: print(t)
```

```
a
└ b
  ┌ e
  | ┌ f
  | ┌ g
  | | ┌ i
  | | ┌ h
  | c
  └ d
```

```
[64]: t.fill_left(['x', 'y'])
```

```
[65]: print(t)
```

```
a
└ x
  ┌ y
  | ┌ f
  | ┌ g
  | | ┌ i
  | | ┌ h
  | c
  └ d
```

```
[66]: t.fill_left(['W', 'V', 'T'])
print(t)
```

```
a
└ W
  ┌ V
  | ┌ T
  | ┌ g
  | | ┌ i
  | | ┌ h
  | c
  └ d
```

B3.2 follow

Open `tree.py` and implement `follow` method:

```
def follow(self, positions):
    """
        RETURN an array of node data, representing a branch from the
        root down to a certain depth.
        The path to follow is determined by given positions, which
        is an array of integer indeces, see example.

        - if provided indeces lead to non-existing nodes, raise ValueError
        - IMPORTANT: *DO NOT* use recursion, use a couple of while instead.
        - IMPORTANT: *DO NOT* attempt to convert siblings to
                    a python list !!!! Doing so will give you less points!

    """

```

Testing: `python3 -m unittest tree_test.FollowTest`

Example:

```
level 01234

      a
      |b
      |c
      | e
      | |f
      | |g
      | | i
      | h
      d

RETURNS
t.follow([])      [a]          root data is always present
t.follow([0])     [a,b]        b is the 0-th child of a
t.follow([2])     [a,d]        d is the 2-nd child of a
t.follow([1,0,2]) [a,c,e,h]  c is the 1-st child of a
                           e is the 0-th child of c
                           h is the 2-nd child of e
t.follow([1,0,1,0]) [a,c,e,g,i] c is the 1-st child of a
                           e is the 0-th child of c
                           g is the 1-st child of e
                           i is the 0-th child of g
```

[]:

2.1.6 Exam - Mon 10, Jun 2019

Scientific Programming - Data Science @ University of Trento

Download exercises and solution

Introduction

- Taking part to this exam erases any vote you had before

What to do

- 1) Download `sciprog-ds-2019-06-10-exam.zip` and extract it on your desktop. Folder content should be like this:

```
sciprog-ds-2019-06-10-FIRSTNAME-LASTNAME-ID
    exam-2019-06-10.ipynb
    stack.py
    stack_test.py
    tree.py
    tree_test.py
    jupman.py
    sciprog.py
```

- 2) Rename `sciprog-ds-2019-06-10-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2019-06-10-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins. If it takes longer, leave it and try another exercise.
- 4) When done:
 - if you have unitn login: zip and send to examina.icts.unitn.it/studente⁷⁵
 - If you don't have unitn login: tell instructors and we will download your work manually

Part A

Open Jupyter and start editing this notebook `exam-2019-06-10.ipynb`

A1 ITEA real estate

You will now analyze public real estates in Trentino, which are managed by ITEA agency. Every real estate has a type, and we will find the type distribution.

Data provider: [ITEA - dati.trentino.it](https://dati.trentino.it/)⁷⁶

A function `load_itea` is given to load the dataset (you don't need to implement it):

⁷⁵ <http://examina.icts.unitn.it/studente>

⁷⁶ <https://dati.trentino.it/dataset/patrimonio-immobiliare>

```
[2]: def load_itea():
    """Loads file data and RETURN a list of dictionaries with the stop times
    """

    import csv
    with open('data/itea.csv', newline='', encoding='latin-1') as csvfile:
        reader = csv.DictReader(csvfile, delimiter=';')
        lst = []
        for d in reader:
            lst.append(d)
    return lst

itea = load_itea()
```

IMPORTANT: look at the dataset by yourself !

Here we show only first 5 rows, but to get a clear picture of the dataset you need to study it a bit by yourself

```
[3]: itea[:5]
[3]: [OrderedDict([('Tipologia', 'ALTRO'),
                  ('Proprietà', 'ITEA'),
                  ('Indirizzo', "Codice unita': 30100049"),
                  ('Frazione', ''),
                  ('Comune', "BASELGA DI PINE")]),
OrderedDict([('Tipologia', 'ALLOGGIO'),
             ('Proprietà', 'ITEA'),
             ('Indirizzo', "Codice unita': 43100011"),
             ('Frazione', ''),
             ('Comune', 'TRENTO')]),
OrderedDict([('Tipologia', 'ALLOGGIO'),
             ('Proprietà', 'ITEA'),
             ('Indirizzo', "Codice unita': 43100002"),
             ('Frazione', ''),
             ('Comune', 'TRENTO')]),
OrderedDict([('Tipologia', 'ALLOGGIO'),
             ('Proprietà', 'ITEA'),
             ('Indirizzo', 'VIALE DELLE ROBINIE 26'),
             ('Frazione', ''),
             ('Comune', 'TRENTO')]),
OrderedDict([('Tipologia', 'ALLOGGIO'),
             ('Proprietà', 'ITEA'),
             ('Indirizzo', 'VIALE DELLE ROBINIE 26'),
             ('Frazione', ''),
             ('Comune', 'TRENTO')])]
```

A1.1 calc_types_hist

Implement function `calc_types_hist` to extract the types ('Tipologia') of ITEA real estate and RETURN a histogram which associates to each type its frequency.

- You will discover there are three types of apartments: 'ALLOGGIO', 'ALLOGGIO DUPLEX' and 'ALLOGGIO MONOLOCALE'. In the resulting histogram you must place only the key 'ALLOGGIO' which will be the sum of all of them.
- Same goes for 'POSTO MACCHINA' (parking lot): there are many of them ('POSTO MACCHINA COMUNE ESTERNO', 'POSTO MACCHINA COMUNE INTERNO', 'POSTO MACCHINA ESTERNO', 'POSTO MACCHINA INTERNO', 'POSTO MACCHINA SOTTO TETTOIA') but we only want to see 'POSTO MACCHINA' as key with the sum of all of them. NOTE: Please don't use 5 ifs, try to come up with some generic code to catch all these cases ..)

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

[4]: `def calc_types_hist(db):`

```
    tipologie = {}
    for diz in db:
        if diz['Tipologia'].startswith('ALLOGGIO'):
            chiave = 'ALLOGGIO'
        elif diz['Tipologia'].startswith('POSTO MACCHINA'):
            chiave = 'POSTO MACCHINA'
        else:
            chiave = diz['Tipologia']

        if chiave in tipologie:
            tipologie[chiave] += 1
        else:
            tipologie[chiave] = 1

    return tipologie
```

`calc_types_hist(itea)`

```

A1.2 calc_types_series

Takes a dictionary histogram and RETURN a list of tuples containing key/value pairs, sorted from most frequent items to least frequent.

HINT: if you don't remember how to sort by an element of a tuple, look at [this example⁷⁷](#) and also in python documentation about sorting.

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[5]: def calc_types_series(hist):
    ret = []
    for key in hist:
        ret.append((key, hist[key]))
```

(continues on next page)

⁷⁷ <https://sciprog.davidleoni.it/visualization/visualization-sol.html#indegree-per-node-sorted>

(continued from previous page)

```
ret.sort(key=lambda c: c[1], reverse=True)
return ret[:10]

tipologie = calc_types_series(calc_types_hist(itea))

tipologie
[5]: [('ALLOGGIO', 10778),
      ('POSTO MACCHINA', 3147),
      ('GARAGE', 2221),
      ('MAGAZZINO', 143),
      ('NEGOZIO', 139),
      ('ALTRO', 64),
      ('SALA / ATTIVITA SOCIALI', 45),
      ('CABINA ELETTRICA', 41),
      ('CANTINA', 40),
      ('UFFICIO', 29)]
```

</div>

```
[5]: def calc_types_series(hist):
    raise Exception('TODO IMPLEMENT ME !')

tipologie = calc_types_series(calc_types_hist(itea))

tipologie
[5]: [('ALLOGGIO', 10778),
      ('POSTO MACCHINA', 3147),
      ('GARAGE', 2221),
      ('MAGAZZINO', 143),
      ('NEGOZIO', 139),
      ('ALTRO', 64),
      ('SALA / ATTIVITA SOCIALI', 45),
      ('CABINA ELETTRICA', 41),
      ('CANTINA', 40),
      ('UFFICIO', 29)]
```

A1.3 Real estates plot

Once you obtained the series as above, plot the first 10 most frequent items, in decreasing order.

- please pay attention to plot title, width and height, axis labels. Everything MUST display in a readable way.
- try also to print nice the labels, if they are too long / overlap like for ‘SALA / ATTIVITA SOCIALI’ put carriage returns in a generic way.

```
[6]: # write here
```

```
<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"
   data-jupman-show="Show solution"
   data-jupman-hide="Hide">Show solution</a><div class="jupman-sol jupman-sol-code" style="display:none">
```

[7]:

```
# SOLUTION

%matplotlib inline
import numpy as np
import matplotlib.pyplot as plt

xs = np.arange(len(tipologie))

xs_labels = [t[0].replace('/', '\n') for t in tipologie]

ys = [t[1] for t in tipologie]

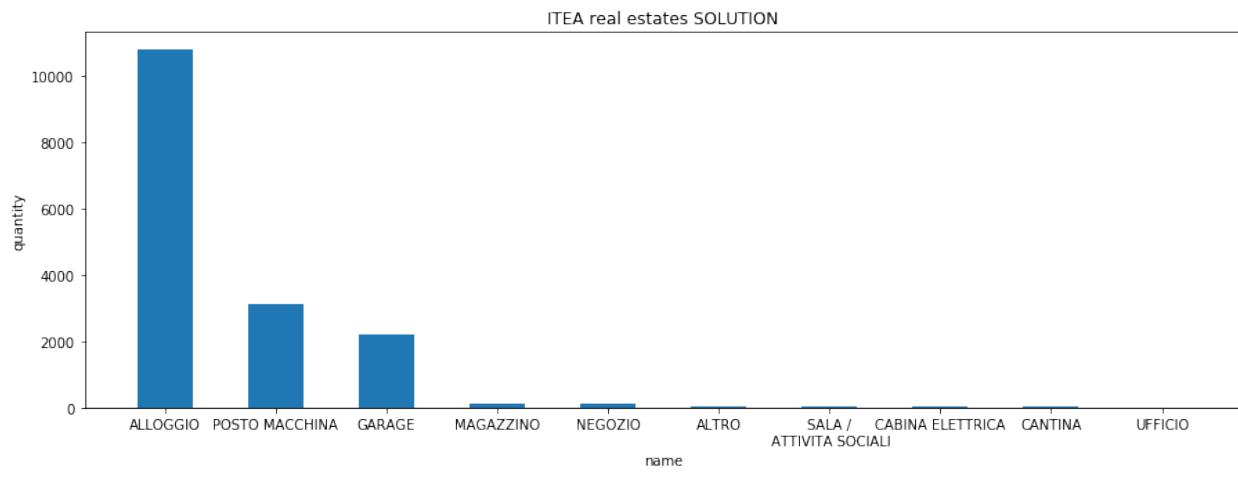

fig = plt.figure(figsize=(15,5))

plt.bar(xs, ys, 0.5, align='center')

plt.title("ITEA real estates SOLUTION")
plt.xticks(xs, xs_labels)

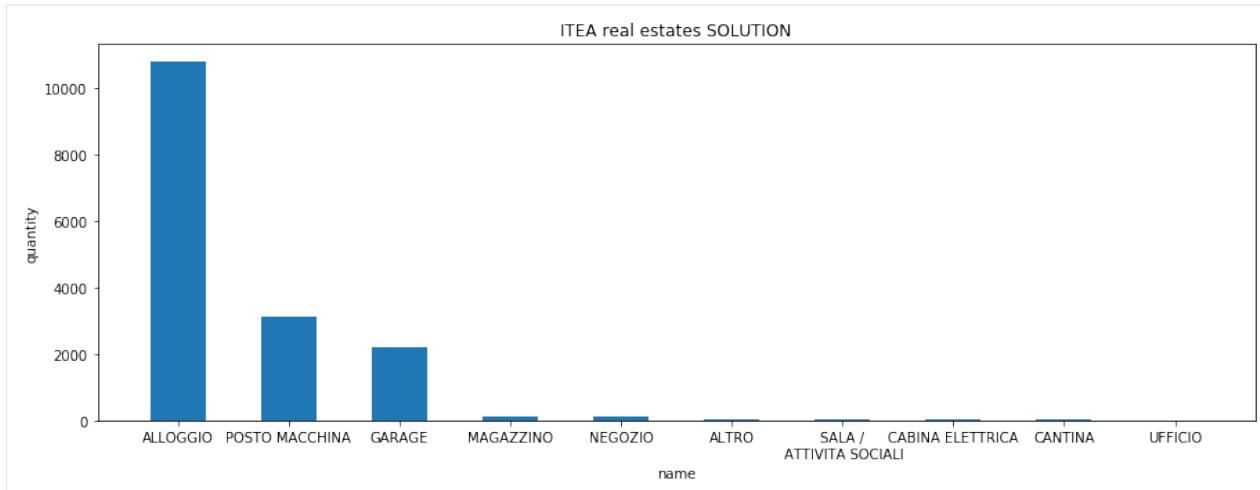

plt.xlabel('name')
plt.ylabel('quantity')

plt.show()
```

</div>

[7]:

A2 Air quality

You will now analyze air_quality in Trentino. You are given a dataset which records various pollutants ('Inquinante') at various stations ('Stazione') in Trentino. Pollutants values can be 'PM10', 'Birossido Zolfo', and a few others. Each station records some set of pollutants. For each pollutant values are recorded ('Valore') 24 times per day.

Data provider: PAT Ag. Provinciale per la protezione dell'Ambiente - dati.trentino.it⁷⁸

A function `load_air_quality` is given to load the dataset (you don't need to implement it):

```
[8]: def load_air_quality():
    """Loads file data and RETURN a list of dictionaries with the stop times
    """

    import csv
    with open('data/air-quality.csv', newline='', encoding='latin-1') as csvfile:
        reader = csv.DictReader(csvfile)
        lst = []
        for d in reader:
            lst.append(d)
    return lst

air_quality = load_air_quality()
```

IMPORTANT 1: look at the dataset by yourself !

Here we show only first 5 rows, but to get a clear picture of the dataset you need to study it a bit by yourself

IMPORTANT 2: EVERY field is a STRING, including 'Valore' !

⁷⁸ <https://dati.trentino.it/dataset/qualita-dell-aria-rilevazioni-delle-stazioni-monitoraggio>

```
[9]: air_quality[:5]
[9]: [OrderedDict([('Stazione', 'Parco S. Chiara'),
                  ('Inquinante', 'PM10'),
                  ('Data', '2019-05-04'),
                  ('Ora', '1'),
                  ('Valore', '17'),
                  ('Unità di misura', 'µg/mc')]),
     OrderedDict([('Stazione', 'Parco S. Chiara'),
                  ('Inquinante', 'PM10'),
                  ('Data', '2019-05-04'),
                  ('Ora', '2'),
                  ('Valore', '19'),
                  ('Unità di misura', 'µg/mc')]),
     OrderedDict([('Stazione', 'Parco S. Chiara'),
                  ('Inquinante', 'PM10'),
                  ('Data', '2019-05-04'),
                  ('Ora', '3'),
                  ('Valore', '17'),
                  ('Unità di misura', 'µg/mc')]),
     OrderedDict([('Stazione', 'Parco S. Chiara'),
                  ('Inquinante', 'PM10'),
                  ('Data', '2019-05-04'),
                  ('Ora', '4'),
                  ('Valore', '15'),
                  ('Unità di misura', 'µg/mc')]),
     OrderedDict([('Stazione', 'Parco S. Chiara'),
                  ('Inquinante', 'PM10'),
                  ('Data', '2019-05-04'),
                  ('Ora', '5'),
                  ('Valore', '13'),
                  ('Unità di misura', 'µg/mc')])]
```

Now implement the following function:

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

```
[10]: def calc_avg_pollution(db):
    """ RETURN a dictionary containing two elements tuples as keys:
        - first tuple element is the station ('Stazione'),
        - second tuple element is the name of a pollutant ('Inquinante')

        To each tuple key, you must associate as value the average for that station
        _and_ pollutant over all days.

    """
    ret = {}
    counts = {}
    for diz in db:
        t = (diz['Stazione'], diz['Inquinante'])
        if t in ret:
            ret[t] += float(diz['Valore'])
            counts[t] += 1
        else:
            ret[t] = float(diz['Valore'])
            counts[t] = 1
```

(continues on next page)

(continued from previous page)

```

for t in ret:
    ret[t] /= counts[t]
return ret

```

Part B

B1 Theory

Let L be a list containing n lists, each of them of size m . Return the computational complexity of function `fun()` with respect to n and m .

Write the solution in separate ``theory.txt`` file

```
def fun(L):
    for r1 in L:
        for r2 in L:
            if r1 != r2 and sum(r1) == sum(r2):
                print("Similar:")
                print(r1)
                print(r2)
```

Show answer<div class="jupman-sol jupman-sol-question" style="display:none">

ANSWER: $\Theta(m \cdot n^2)$

</div>

B2 WStack

Using a text editor, open file `stack.py`. You will find a `WStack` class skeleton which represents a simple stack that can only contain integers.

B2.1 implement class `WStack`

Fill in missing methods in class `WStack` in the order they are presented so to have a `.weight()` method that returns the total sum of integers in the stack in $O(1)$ time.

Example:

```
[11]: from stack_sol import *
[12]: s = WStack()
[13]: print(s)
WStack: weight=0 elements=[]
[14]: s.push(7)
[15]: print(s)
WStack: weight=7 elements=[7]
[16]: s.push(4)
[17]: print(s)
WStack: weight=11 elements=[7, 4]
[18]: s.push(2)
[19]: s.pop()
[19]: 2
[20]: print(s)
WStack: weight=11 elements=[7, 4]
```

B2.2 accumulate

Implement function `accumulate`:

```
def accumulate(stack1, stack2, min_amount):
    """ Pushes on stack2 elements taken from stack1 until the weight of
    stack2 is equal or exceeds the given min_amount

    - if the given min_amount cannot possibly be reached because
      stack1 has not enough weight, raises early ValueError without
      changing stack1.
```

(continues on next page)

(continued from previous page)

- DO NOT access internal fields of stacks, only use class methods.
 - MUST perform in $O(n)$ where n is the size of stack1
 - NOTE: this function is defined *outside* the class !
- """

Testing: python -m unittest stacks_test.AccumulateTest

Example:

[21]:

```
s1 = WStack()

print(s1)

WStack: weight=0 elements=[]
```

[22]: s1.push(2)
s1.push(9)
s1.push(5)
s1.push(3)

[23]: print(s1)

WStack: weight=19 elements=[2, 9, 5, 3]

[24]: s2 = WStack()
print(s2)

WStack: weight=0 elements=[]

[25]: s2.push(1)
s2.push(7)
s2.push(4)

[26]: print(s2)

WStack: weight=12 elements=[1, 7, 4]

[27]: # attempts to reach in s2 a weight of at least 17

[28]: accumulate(s1,s2,17)

[29]: print(s1)

WStack: weight=11 elements=[2, 9]

Two top elements were taken from s1 and now s2 has a weight of 20, which is ≥ 17

[30]: print(s2)

```
WStack: weight=20 elements=[1, 7, 4, 3, 5]
```

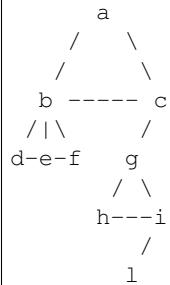

B3 GenericTree

Open file `tree.py` in a text editor and read following instructions.

B3.1 is_triangle

A *triangle* is a node which has *exactly* two children.

Let's see some example:

The tree above can also be represented like this:

```
a
|---b
|   |---d
|   |---e
|   |---f
|---c
    |---g
        |---h
            |---i
                |---l
```

- node *a* is a triangle because has *exactly* two children *b* and *c*, note it doesn't matter if *b* or *c* have children
- *b* is *not* a triangle (has 3 children)
- *c* and *i* are *not* triangles (have only 1 child)
- *g* is a triangle as it has *exactly* two children *h* and *i*
- *d*, *e*, *f*, *h* and *l* are not triangles, because they have zero children

Now implement this method:

```
def is_triangle(self, elems):
    """ RETURN True if this node is a triangle matching the data
        given by list elems.

        In order to match:
        - first list item must be equal to this node data
        - second list item must be equal to this node first child data
        - third list item must be equal to this node second child data
    """

    pass
```

(continues on next page)

(continued from previous page)

```
    - if elems has less than three elements, raises ValueError
"""

```

Testing: python -m unittest tree_test.IsTriangleTest**Examples:**

```
[31]: from tree_test import gt
```

```
[32]: # this is the tree from the example above

tb = gt('b', gt('d', gt('e'), gt('f')))
tg = gt('g', gt('h'), gt('i', gt('l')))
ta = gt('a', tb, gt('c', tg))

ta.is_triangle(['a', 'b', 'c'])
```

```
[32]: True
```

```
[33]: ta.is_triangle(['b', 'c', 'a'])
```

```
[33]: False
```

```
[34]: tb.is_triangle(['b', 'd', 'e'])
```

```
[34]: False
```

```
[35]: tg.is_triangle(['g', 'h', 'i'])
```

```
[35]: True
```

```
[36]: tg.is_triangle(['g', 'i', 'h'])
```

```
[36]: False
```

B3.2 has_triangle

Implement this method:

```
def has_triangle(self, elems):
    """ RETURN True if this node *or one of its descendants* is a triangle
        matching given elems. Otherwise, return False.

        - a recursive solution is acceptable
    """

```

Testing: python -m unittest tree_test.HasTriangleTest**Examples:**

```
[37]: # example tree seen at the beginning

tb = gt('b', gt('d', gt('e'), gt('f')))
tg = gt('g', gt('h'), gt('i', gt('l')))
```

(continues on next page)

(continued from previous page)

```
tc = gt('c', tg)
ta = gt('a', tb, tc)

ta.has_triangle(['a', 'b', 'c'])

[37]: True

[38]: ta.has_triangle(['a', 'c', 'b'])

[38]: False

[39]: ta.has_triangle(['b', 'c', 'a'])

[39]: False

[40]: tb.is_triangle(['b', 'd', 'e'])

[40]: False

[41]: tg.has_triangle(['g', 'h', 'i'])

[41]: True

[42]: tc.has_triangle(['g', 'h', 'i']) # check recursion

[42]: True

[43]: ta.has_triangle(['g', 'h', 'i']) # check recursion

[43]: True
```

2.1.7 Exam - Tue 02, July 2019

Scientific Programming - Data Science Master @ University of Trento

[Download exercises and solution](#)

[Introduction](#)

- Taking part to this exam erases any vote you had before

Grading

- **Correct implementations:** Correct implementations with the required complexity grant you full grade.
- **Partial implementations:** Partial implementations *might* still give you a few points. If you just can't solve an exercise, try to solve it at least for some subcase (i.e. array of fixed size 2) commenting why you did so.
- **Bonus point:** One bonus point can be earned by writing stylish code. You got style if you:
 - do not infringe the [Commandments](#)⁷⁹
 - write [pythonic code](#)⁸⁰
 - avoid convoluted code like i.e.

```
if x > 5:
    return True
else:
    return False
```

when you could write just

```
return x > 5
```

Valid code

WARNING: MAKE SURE ALL EXERCISE FILES AT LEAST COMPILE !!! 10 MINS BEFORE THE END OF THE EXAM I WILL ASK YOU TO DO A FINAL CLEAN UP OF THE CODE

WARNING: ONLY IMPLEMENTATIONS OF THE PROVIDED FUNCTION SIGNATURES WILL BE EVALUATED !!!!!!!!

For example, if you are given to implement:

```
def f(x):
    raise Exception("TODO implement me")
```

and you ship this code:

```
def my_f(x):
    # a super fast, correct and stylish implementation

def f(x):
    raise Exception("TODO implement me")
```

We will assess only the latter one `f(x)`, and conclude it doesn't work at all :P !!!!!!!

Helper functions

Still, you are allowed to define any extra helper function you might need. If your `f(x)` implementation calls some other function you defined like `my_f` here, it is ok:

⁷⁹ <https://sciprog.davidleoni.it/commandments.html>

⁸⁰ <http://docs.python-guide.org/writing/style>

```
# Not called by f, will get ignored:  
def my_g(x):  
    # bla  
  
# Called by f, will be graded:  
def my_f(y,z):  
    # bla  
  
def f(x):  
    my_f(x, 5)
```

How to edit and run

To edit the files, you can use any editor of your choice, you can find them under *Applications->Programming*:

- **Visual Studio Code**
- Editra is easy to use, you can find it under *Applications->Programming->Editra*.
- Others could be *GEdit* (simpler), or *PyCharm* (more complex).

To run the tests, use **the Terminal** which can be found in *Accessories -> Terminal*

IMPORTANT: Pay close attention to the comments of the functions.

WARNING: *DON'T* modify function signatures! Just provide the implementation.

WARNING: *DON'T* change the existing test methods, just add new ones !!! You can add as many as you want.

WARNING: *DON'T* create other files. If you still do it, they won't be evaluated.

Debugging

If you need to print some debugging information, you are allowed to put extra print statements in the function bodies.

WARNING: even if print statements are allowed, be careful with prints that might break your function!

For example, avoid stuff like this:

```
x = 0  
print(1/x)
```

What to do

- 1) Download `sciprog-ds-2019-07-02-exam.zip` and extract it on your desktop. Folder content should be like this:

```
sciprog-ds-2019-07-02-FIRSTNAME-LASTNAME-ID
    exam-2019-07-02.ipynb
    theory.txt
    linked_sort.py
    linked_sort_test.py
    stacktris.py
    stacktris_test.py
    jupman.py
    sciprog.py
```

- 2) Rename `sciprog-ds-2019-07-02-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2019-07-02-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise.

- 4) When done:

- if you have unitn login: zip and send to examina.icts.unitn.it/studente⁸¹
- If you don't have unitn login: tell instructors and we will download your work manually

Part A

Open Jupyter and start editing this notebook `exam-2019-07-02.ipynb`

A1 Botteghe storiche

You will work on the dataset of "Botteghe storiche del Trentino" (small shops, workshops of Trentino)

Data provider: Provincia Autonoma di Trento - [dati.trentino.it](https://dati.trentino.it/dataset/botteghe-storiche-del-trentino)⁸²

A function `load_botteghe` is given to load the dataset (you don't need to implement it):

```
[2]: def load_botteghe():
    """Loads file data and RETURN a list of dictionaries with the botteghe dati
    """

    import csv
    with open('data/botteghe.csv', newline='', encoding='utf-8') as csvfile:
        reader = csv.DictReader(csvfile, delimiter=',')
        lst = []
        for d in reader:
            lst.append(d)
    return lst

botteghe = load_botteghe()
```

⁸¹ <http://examina.icts.unitn.it/studente>

⁸² <https://dati.trentino.it/dataset/botteghe-storiche-del-trentino>

IMPORTANT: look at the dataset !

Here we show only first 5 rows, but to get a clear picture of the dataset you should explore it further.

```
[3]: botteghe[:5]
[3]: [OrderedDict([('Numero', '1'),
                  ('Insegna', 'BAZZANELLA RENATA'),
                  ('Indirizzo', 'Via del Lagorai'),
                  ('Civico', '30'),
                  ('Comune', 'Sover'),
                  ('Cap', '38068'),
                  ('Frazione/Località', 'Piscine di Sover'),
                  ('Note', 'generi misti, bar - ristorante'))),
     OrderedDict([('Numero', '2'),
                  ('Insegna', 'CONFEZIONI MONTIBELLER S.R.L.'),
                  ('Indirizzo', 'Corso Ausugum'),
                  ('Civico', '48'),
                  ('Comune', 'Borgo Valsugana'),
                  ('Cap', '38051'),
                  ('Frazione/Località', ''),
                  ('Note', 'esercizio commerciale'))),
     OrderedDict([('Numero', '3'),
                  ('Insegna', 'FOTOGRAFICA TRINTINAGLIA UMBERTO S.N.C.'),
                  ('Indirizzo', 'Largo Dordi'),
                  ('Civico', '8'),
                  ('Comune', 'Borgo Valsugana'),
                  ('Cap', '38051'),
                  ('Frazione/Località', ''),
                  ('Note', 'esercizio commerciale, attività artigianale'))),
     OrderedDict([('Numero', '4'),
                  ('Insegna', 'BAR SERAFINI DI MINATI RENZO'),
                  ('Indirizzo', ''),
                  ('Civico', '24'),
                  ('Comune', 'Grigno'),
                  ('Cap', '38055'),
                  ('Frazione/Località', 'Serafini'),
                  ('Note', 'esercizio commerciale'))),
     OrderedDict([('Numero', '6'),
                  ('Insegna', 'SEMBENINI GINO & FIGLI S.R.L.'),
                  ('Indirizzo', 'Via S. Francesco'),
                  ('Civico', '35'),
                  ('Comune', 'Riva del Garda'),
                  ('Cap', '38066'),
                  ('Frazione/Località', ''),
                  ('Note', '')])]
```

We would like to know which different categories of *bottega* there are, and count them. Unfortunately, there is no specific field for *Categoria*, so we will need to extract this information from other fields such as *Insegna* and *Note*. For example, this *Insegna* contains the category **BAR**, while the *Note* (*commercial enterprise*) is a bit too generic to be useful:

```
'Insegna': 'BAR SERAFINI DI MINATI RENZO',
'Note': 'esercizio commerciale',
```

while this other *Insegna* contains just the owner name and *Note* holds both the categories **bar** and **ristorante**:

```
'Insegna': 'BAZZANELLA RENATA',
'Note': 'generi misti, bar - ristorante',
```

As you see, data is non uniform:

- sometimes the category is in the Insegna
- sometimes is in the Note
- sometimes is in both
- sometimes is lowercase
- sometimes is uppercase
- sometimes is single
- sometimes is multiple (bar - ristorante)

First we want to extract all categories we can find, and rank them according their frequency, from most frequent to least frequent.

To do so, you need to

- count all words you can find in both Insegna and Note fields, and sort them. Note you need to normalize the uppercase.
- consider a category relevant if it is present at least 11 times in the dataset.
- filter non relevant words: some words like prepositions, type of company ('S.N.C', S.R.L., ..), etc will appear a lot, and will need to be ignored. To detect them, you are given a list called stopwords.

NOTE: the rules above do not actually extract all the categories, for the sake of the exercise we only keep the most frequent ones.

A1.1 rank_categories

```
<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"
data-jupman-show="Show solution"
data-jupman-hide="Hide">Show solution</a><div class="jupman-sol jupman-sol-code" style="display:none">
```

```
[4]: def rank_categories(db, stopwords):
    ret = {}
    for diz in db:
        parole = diz['Insegna'].split(" ") + diz['Note'].upper().split(" ")
        for parola in parole:
            if parola in ret and not parola in stopwords:
                ret[parola] += 1
            else:
                ret[parola] = 1
    return sorted([(key, val) for key, val in ret.items() if val > 10], key=lambda c:c[1], reverse=True)

stopwords = [
    'S.N.C.', 'SNC', 'S.A.S.', 'S.R.L.', 'S.C.A.R.L.', 'SCARL', 'S.A.S',
    'COMMERCIALE', 'FAMIGLIA', 'COOPERATIVA',
    '&', 'C.', 'ESERCIZIO',
    'IL', 'DE', 'DI', 'A', 'DA', 'E', 'LA', 'AL', 'DEL', 'ALLA', ]
categories = rank_categories(botteghe, stopwords)
```

(continues on next page)

(continued from previous page)

categories

```
[4]: [ ('BAR', 191),
      ('RISTORANTE', 150),
      ('HOTEL', 67),
      ('ALBERGO', 64),
      ('MACELLERIA', 27),
      ('PANIFICIO', 22),
      ('CALZATURE', 21),
      ('FARMACIA', 21),
      ('ALIMENTARI', 20),
      ('PIZZERIA', 16),
      ('SPORT', 16),
      ('TABACCHI', 12),
      ('FERRAMENTA', 12),
      ('BAZAR', 11)]
```

</div>

```
[4]: def rank_categories(db, stopwords):
        raise Exception('TODO IMPLEMENT ME !')

stopwords = [
    'S.N.C.', 'SNC', 'S.A.S.', 'S.R.L.', 'S.C.A.R.L.', 'SCARL', 'S.A.S',
    'COMMERCIALE', 'FAMIGLIA', 'COOPERATIVA',
    '-', '&', 'C.', 'ESERCIZIO',
    'IL', 'DE', 'DI', 'A', 'DA', 'E', 'LA', 'AL', 'DEL', 'ALLA', ]
categories = rank_categories(botteghe, stopwords)
```

categories

```
[4]: [ ('BAR', 191),
      ('RISTORANTE', 150),
      ('HOTEL', 67),
      ('ALBERGO', 64),
      ('MACELLERIA', 27),
      ('PANIFICIO', 22),
      ('CALZATURE', 21),
      ('FARMACIA', 21),
      ('ALIMENTARI', 20),
      ('PIZZERIA', 16),
      ('SPORT', 16),
      ('TABACCHI', 12),
      ('FERRAMENTA', 12),
      ('BAZAR', 11)]
```

A1.2 plot

Now plot the 10 most frequent categories. Please pay attention to plot title, width and height, axis labels. Everything MUST display in a readable way.

```
[5]: # write here
```

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[6]:
```

```
# SOLUTION

%matplotlib inline
import numpy as np
import matplotlib.pyplot as plt

cats = categories[:10]

xs = np.arange(len(cats))

xs_labels = [t[0] for t in cats]

ys = [t[1] for t in cats]

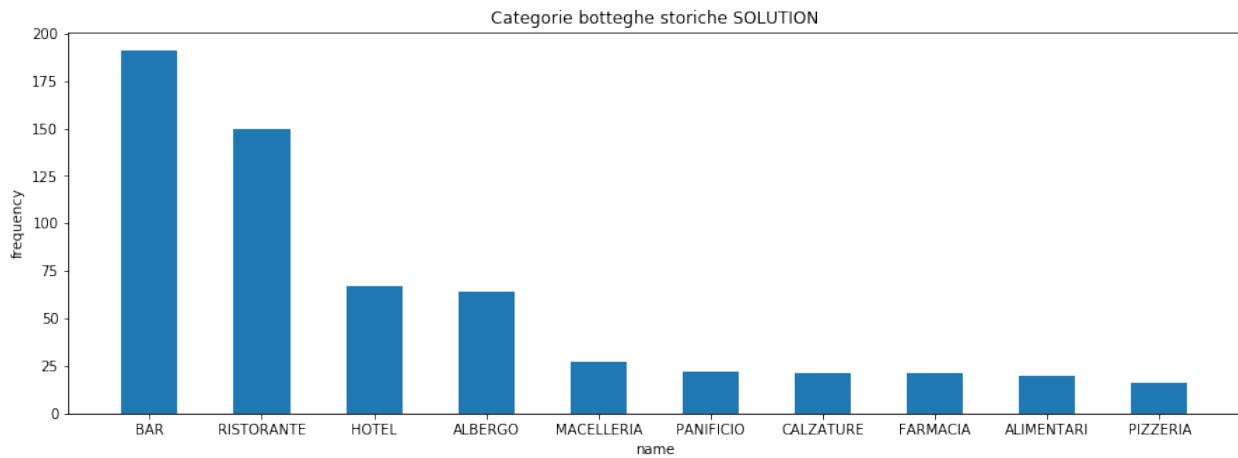

fig = plt.figure(figsize=(15,5))

plt.bar(xs, ys, 0.5, align='center')

plt.title("Categorie botteghe storiche SOLUTION")
plt.xticks(xs, xs_labels)

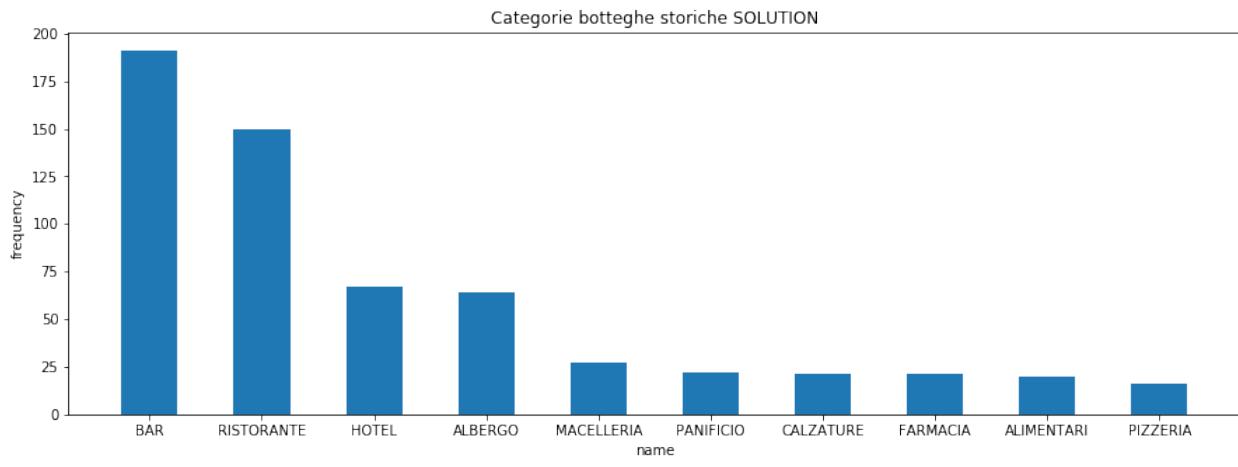

plt.xlabel('name')
plt.ylabel('frequency')

plt.show()
```

</div>

[6] :

A1.3 enrich

Once you found the categories, implement function `enrich`, which takes the db and previously computed categories, and RETURN a NEW DB where the dictionaries are enriched with a new field `Categorie`, which holds a list of the categories a particular *bottega* belongs to.

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[7]: def enrich(db, categories):
    ret = []
    for diz in db:
        new_diz = {key:val for key, val in diz.items()}
        new_diz['Categorie'] = []
        for cat in categories:
            if cat[0] in diz['Insegna'].upper() or cat[0] in diz['Note'].upper():
                new_diz['Categorie'].append(cat[0])
        ret.append(new_diz)
    return ret
```

new_db = enrich(botteghe, rank_categories(botteghe, stopwords))

new_db[:6] #NOTE here we only show a sample

```
[7]: [{"Numero": '1',
  'Insegna': 'BAZZANELLA RENATA',
  'Indirizzo': 'Via del Lagorai',

A2 dump

The multinational ToxiCorp wants to hire you for devising an automated truck driver which will deposit highly contaminated waste in the illegal dumps they own worldwide. You find it ethically questionable, but they pay well, so you accept.

A dump is modelled as a rectangular region of dimensions `nrow` and `ncol`, implemented as a list of lists matrix. Every cell i, j contains the tons of waste present, and can contain *at most* 7 tons of waste.

The dumpster truck will transport `q` tons of waste, and try to fill the dump by depositing waste in the first row, filling each cell up to 7 tons. When the first row is filled, it will proceed to the second one *from the left*, then to the third one again *from the left* until there is no waste to dispose of.

Function `dump(m, q)` takes as input the dump `mat` and the number of tons `q` to dispose of, and RETURN a NEW list representing a plan with the sequence of tons to dispose. If waste to dispose exceeds dump capacity, raises `ValueError`.

NOTE: the function does **not** modify the matrix

Example:

```
m = [
    [5, 4, 6],
    [4, 7, 1],
    [3, 2, 6],
    [3, 6, 2],
]

dump(m, 22)

[2, 3, 1, 3, 0, 6, 4, 3]
```

For first row we dispose of 2,3,1 tons in three cells, for second row we dispose of 3,0,6 tons in three cells, for third row we only dispose 4,3 tons in two cells as limit `q=22` is reached.

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[8]: def dump(mat, q):

    rem = q
    ret = []

    for riga in mat:
        for j in range(len(riga)):
            cellfill = 7 - riga[j]
            unload = min(cellfill, rem)
            rem -= unload

            if rem > 0:
                ret.append(unload)
            else:
                if unload > 0:
                    ret.append(unload)
    return ret

    if rem > 0:
        raise ValueError("Couldn't fill the dump, %s tons remain!")
```

(continues on next page)

(continued from previous page)

```
m1 = [
    [5]
]

assert dump(m1, 0) == [] # nothing to dump

m2 = [
    [4]
]

assert dump(m2, 2) == [2]

m3 = [
    [5, 4]
]

assert dump(m3, 3) == [2, 1]

m3 = [
    [5, 7, 3]
]

assert dump(m3, 3) == [2, 0, 1]

m5 = [
    [2, 5],    # 5 2
    [4, 3]     # 3 1
]

assert dump(m5, 11) == [5, 2, 3, 1]

m6 = [          # tons to dump in each cell
    [5, 4, 6],   # 2 3 1
    [4, 7, 1],   # 3 0 6
    [3, 2, 6],   # 4 3 0
    [3, 6, 2],   # 0 0 0
]

assert dump(m6, 22) == [2, 3, 1, 3, 0, 6, 4, 3]

try:
    dump ([[5]], 10)
    raise Exception("Should have failed !")
except ValueError:
    pass
```

</div>

```
[8]: def dump(mat, q):
    raise Exception('TODO IMPLEMENT ME !')
```

(continues on next page)

(continued from previous page)

```

m1 = [
    [5]
]

assert dump(m1, 0) == [] # nothing to dump

m2 = [
    [4]
]

assert dump(m2, 2) == [2]

m3 = [
    [5, 4]
]

assert dump(m3, 3) == [2, 1]

m3 = [
    [5, 7, 3]
]

assert dump(m3, 3) == [2, 0, 1]

m5 = [
    [2, 5],    # 5 2
    [4, 3]     # 3 1
]

assert dump(m5, 11) == [5, 2, 3, 1]

m6 = [          # tons to dump in each cell
    [5, 4, 6],   # 2 3 1
    [4, 7, 1],   # 3 0 6
    [3, 2, 6],   # 4 3 0
    [3, 6, 2],   # 0 0 0
]

assert dump(m6, 22) == [2, 3, 1, 3, 0, 6, 4, 3]

try:
    dump ([[5]], 10)
    raise Exception("Should have failed !")
except ValueError:
    pass

```

Part B

B1 Theory

Write the solution in separate ``theory.txt`` file

Let L1 and L2 be two lists containing n lists, each of them of size n. Compute the computational complexity of function fun () with respect to n.

```
def fun(L1,L2):
    for r1 in L1:
        for val in r1:
            for r2 in L2:
                if val == sum(r2):
                    print(val)
```

Show answer<div class="jupman-sol jupman-sol-question" style="display:none">

ANSWER: $\Theta(n^4)$

</div>

B2 Linked List sorting

Open a text editor and edit file linked_sort.py

B2.1 bubble_sort

You will implement bubble sort on a LinkedList.

```
def bubble_sort(self):
    """ Sorts in-place this linked list using the method of bubble sort

        - MUST execute in O(n^2) where n is the length of the linked list
    """
```

Testing: python3 -m unittest linked_sort_test.BubbleSortTest

As a reference, you can look at this example_bubble implementation below that operates on regular python lists. Basically, you will have to translate the for cycles into two suitable while and use node pointers.

NOTE: this version of the algorithm is inefficient as we do not use j in the inner loop: your linked list implementation can have this inefficiency as well.

```
[9]: def example_bubble(plist):
    for j in range(len(plist)):
        for i in range(len(plist)):
            if i + 1 < len(plist) and plist[i] > plist[i+1]:
                temp = plist[i]
                plist[i] = plist[i+1]
                plist[i+1] = temp

my_list = [23, 34, 55, 32, 7777, 98, 3, 2, 1]
example_bubble(my_list)
print(my_list)
```

```
[1, 2, 3, 23, 32, 34, 55, 98, 7777]
```

B2.2 merge

Implement this method:

```
def merge(self, l2):
    """ Assumes this linkedlist and l2 linkedlist contain integer numbers
        sorted in ASCENDING order, and RETURN a NEW LinkedList with
        all the numbers from this and l2 sorted in DESCENDING order

    IMPORTANT 1: *MUST* EXECUTE IN O(n1+n2) TIME where n1 and n2 are
        the sizes of this and l2 linked_list, respectively

    IMPORTANT 2: *DO NOT* attempt to convert linked lists to
        python lists!
    """

```

Testing: python3 -m unittest linked_sort_test.MergeTest

B3 Stacktris

Open a text editor and edit file stacktris.py

A Stacktris is a data structure that operates like the famous game Tetris, with some restrictions:

- Falling pieces can be either of length 1 or 2. We call them 1-block and 2-block respectively
- The pit has a fixed width of 3 columns
- 2-blocks can only be in horizontal

We print a Stacktris like this:

```
\ j 012
i
4 | 11|      # two 1-block
3 | 22|      # one 2-block
2 | 1 |      # one 1-block
1 |22|      # one 2-block
0 |1 1|      # on the ground there are two 1-block
```

In Python, we model the Stacktris as a class holding in the variable `_stack` a list of lists of integers, which models the pit:

```
class Stacktris:

    def __init__(self):
        """ Creates a Stacktris
        """
        self._stack = []
```

So in the situation above the `_stack` variable would look like this (notice row order is inverted with respect to the print)

```
[  
    [1,0,1],  
    [2,2,0],  
    [0,1,0],  
    [0,2,2],  
    [0,1,1],  
]
```

The class has three methods of interest which you will implement, `drop1(j)`, `drop2h(j)` and `_shorten`

Example

Let's see an example:

```
[10]: from stacktris_sol import *  
  
st = Stacktris()
```

At the beginning the pit is empty:

```
[11]: st  
  
[11]: Stacktris:  
EMPTY
```

We can start by dropping from the ceiling a block of dimension 1 into the last column at index $j=2$. By doing so, a new row will be created, and will be a list containing the numbers `[0, 0, 1]`

IMPORTANT: zeroes are not displayed

```
[12]: st.drop1(2)  
  
DEBUG: Stacktris:  
| 1 |  
  
[12]: []
```

Now we drop an horizontal block of dimension 2 (a 2-block) having the leftmost block at column $j=1$. Since below in the pit there is already the 1 block we previously put, the new block will fall and stay upon it. Internally, we will add a new row as a python list containing the numbers `[0, 2, 2]`

```
[13]: st.drop2h(1)  
  
DEBUG: Stacktris:  
| 22 |  
| 1 |  
  
[13]: []
```

We see the zeroth column is empty, so if we drop there a 1-block it will fall to the ground. Internally, the zeroth list will become `[1, 0, 1]`:

```
[14]: st.drop1(0)  
  
DEBUG: Stacktris:  
| 22 |  
| 1 1 |
```

[14]: []

Now we drop again a 2-block at column $j=2$, on top of the previously laid one. This will add a new row as list $[0, 2, 2]$.

[15]: st.drop2h(1)

```
DEBUG: Stacktris:
| 22|
| 22|
|1 1|
```

[15]: []

In the game Tetris, when a row becomes completely filled it disappears. So if we drop a 1-block to the leftmost column, the mid line should be removed.

NOTE: The messages on the console are just debug print, the function `drop1` only returns the extracted line $[1, 2, 2]$:

[16]: st.drop1(0)

```
DEBUG: Stacktris:
| 22|
|122|
|1 1|
DEBUG: POPPING [1, 2, 2]
DEBUG: Stacktris:
| 22|
|1 1|
```

[16]: [1, 2, 2]

Now we insert another 2-block starting at $j=0$. It will fall upon the previously laid one:

[17]: st.drop2h(0)

```
DEBUG: Stacktris:
|22 |
| 22|
|1 1|
```

[17]: []

We can complete the topmost row by dropping a 1-block to the rightmost column. As a result, the row will be removed from the stack and the row will be returned by the call to `drop1`:

[18]: st.drop1(2)

```
DEBUG: Stacktris:
|221|
| 22|
|1 1|
DEBUG: POPPING [2, 2, 1]
DEBUG: Stacktris:
| 22|
```

(continues on next page)

(continued from previous page)

```
|1 1|  
[18]: [2, 2, 1]
```

Another line completion with a `drop1` at column $j=0$:

```
[19]: st.drop1(0)  
  
DEBUG: Stacktris:  
|122|  
|1 1|  
  
DEBUG: POPPING [1, 2, 2]  
DEBUG: Stacktris:  
|1 1|  
  
[19]: [1, 2, 2]
```

We can finally empty the `Stacktris` by dropping a 1-block in the mod column:

```
[20]: st.drop1(1)  
  
DEBUG: Stacktris:  
|111|  
  
DEBUG: POPPING [1, 1, 1]  
DEBUG: Stacktris:  
EMPTY  
  
[20]: [1, 1, 1]
```

B3.1 `_shorten`

Start by implementing this private method:

```
def _shorten(self):  
    """ Scans the Stacktris from top to bottom searching for a completely filled line:  
        - if found, remove it from the Stacktris and return it as a list.  
        - if not found, return an empty list.  
    """
```

If you wish, you can add debug prints but they are not mandatory

Testing: `python3 -m unittest stacktris_test.ShortenTest`

B3.2 drop1

Once you are done with the previous function, implement drop1 method:

NOTE: In the implementation, feel free to call the previously implemented _shorten method.

```
def drop1(self, j):
    """ Drops a 1-block on column j.

        - If another block is found, place the 1-block on top of that block,
          otherwise place it on the ground.

        - If, after the 1-block is placed, a row results completely filled, removes
          the row and RETURN it. Otherwise, RETURN an empty list.

        - if index `j` is outside bounds, raises ValueError
    """

```

Testing: python3 -m unittest stacktris_test.Drop1Test

B3.3 drop2h

Once you are done with the previous function, implement drop2 method:

```
def drop2h(self, j):
    """ Drops a 2-block horizontally with left block on column j.

        - If another block is found, place the 2-block on top of that block,
          otherwise place it on the ground.

        - If, after the 2-block is placed, a row results completely filled,
          removes the row and RETURN it. Otherwise, RETURN an empty list.

        - if index `j` is outside bounds, raises ValueError
    """

```

Testing: python3 -m unittest stacktris_test.Drop2hTest

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">
</div>

2.1.8 Exam - Mon 26, Aug 2019

Scientific Programming - Data Science @ University of Trento

Download exercises and solution

Introduction

- Taking part to this exam erases any vote you had before

Grading

- **Correct implementations:** Correct implementations with the required complexity grant you full grade.
- **Partial implementations:** Partial implementations *might* still give you a few points. If you just can't solve an exercise, try to solve it at least for some subcase (i.e. array of fixed size 2) commenting why you did so.
- **Bonus point:** One bonus point can be earned by writing stylish code. You got style if you:

- do not infringe the Commandments⁸³
- write pythonic code⁸⁴
- avoid convoluted code like i.e.

```
if x > 5:  
    return True  
else:  
    return False
```

when you could write just

```
return x > 5
```

Valid code

WARNING: MAKE SURE ALL EXERCISE FILES AT LEAST COMPILE !!! 10 MINS BEFORE THE END OF THE EXAM I WILL ASK YOU TO DO A FINAL CLEAN UP OF THE CODE

WARNING: ONLY IMPLEMENTATIONS OF THE PROVIDED FUNCTION SIGNATURES WILL BE EVALUATED !!!!!!!!

For example, if you are given to implement:

```
def f(x):  
    raise Exception("TODO implement me")
```

and you ship this code:

```
def my_f(x):  
    # a super fast, correct and stylish implementation  
  
def f(x):  
    raise Exception("TODO implement me")
```

⁸³ <https://sciprog.davidleoni.it/commandments.html>

⁸⁴ <http://docs.python-guide.org/writing/style>

We will assess only the latter one `f(x)`, and conclude it doesn't work at all :P !!!!!!

Helper functions

Still, you are allowed to define any extra helper function you might need. If your `f(x)` implementation calls some other function you defined like `my_f` here, it is ok:

```
# Not called by f, will get ignored:  
def my_g(x):  
    # bla  
  
# Called by f, will be graded:  
def my_f(y, z):  
    # bla  
  
def f(x):  
    my_f(x, 5)
```

How to edit and run

To edit the files, you can use any editor of your choice, you can find them under *Applications->Programming*:

- **Visual Studio Code**
- Editra is easy to use, you can find it under *Applications->Programming->Editra*.
- Others could be *GEdit* (simpler), or *PyCharm* (more complex).

To run the tests, use **the Terminal** which can be found in *Accessories -> Terminal*

IMPORTANT: Pay close attention to the comments of the functions.

WARNING: *DON'T* modify function signatures! Just provide the implementation.

WARNING: *DON'T* change the existing test methods, just add new ones !!! You can add as many as you want.

WARNING: *DON'T* create other files. If you still do it, they won't be evaluated.

Debugging

If you need to print some debugging information, you are allowed to put extra print statements in the function bodies.

WARNING: even if print statements are allowed, be careful with prints that might break your function!

For example, avoid stuff like this:

```
x = 0
print(1/x)
```

What to do

- 1) Download `sciprog-ds-2019-08-26-exam.zip` and extract it on your desktop. Folder content should be like this:

```
sciprog-ds-2019-08-26-FIRSTNAME-LASTNAME-ID
exam-2019-08-26.ipynb
theory.txt
backpack.py
backpack_test.py
concert.py
concert_test.py
jupman.py
sciprog.py
```

- 2) Rename `sciprog-ds-2019-08-26-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2019-08-26-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins.
If it takes longer, leave it and try another exercise.
- 4) When done:
 - if you have unitn login: zip and send to `examina.icts.unitn.it/studente`⁸⁵
 - If you don't have unitn login: tell instructors and we will download your work manually

Part A - University of Trento staff

Open Jupyter and start editing this notebook `exam-2019-08-26.ipynb`

You will work on the dataset of *University of Trento staff*, modified so not to contain names or surnames.

Data provider: [University of Trento](#)⁸⁶

A function `load_data` is given to load the dataset (you don't need to implement it):

```
[1]: import json

def load_data():
    with open('data/2019-06-30-persone-en-stripped.json', encoding='utf-8') as json_file:
        data = json.load(json_file)
    return data

unitn = load_data()
```

⁸⁵ <http://examina.icts.unitn.it/studente>

⁸⁶ <https://dati.trentino.it/dataset/personale-accademico-e-tecnico-amministrativo-dell-universita-di-trento>

IMPORTANT: look at the dataset !

Here we show only first 2 rows, but to get a clear picture of the dataset you should explore it further.

The dataset contains a list of employees, each of whom may have one or more positions, in one or more university units. Each unit is identified by a code like STO0000435:

```
[2]: unitn[:2]

[2]: [{"givenName": "NAME-1",
  "phone": ["0461 283752"],
  "identifier": "eb9139509dc40d199b6864399b7e805c",
  "familyName": "SURNAME-1",
  "positions": [{"unitIdentifier": "STO0008929",
    "role": "Staff",
    "unitName": "Student Support Service: Economics, Law and International Studies"}]}
→,
{"givenName": "NAME-2",
  "phone": ["0461 281521"],
  "identifier": "b6292ffe77167b31e856d2984544e45b",
  "familyName": "SURNAME-2",
  "positions": [{"unitIdentifier": "STO0000435",
    "role": "Associate professor",
    "unitName": "Doctoral programme - Physics"},
   {"unitIdentifier": "STO0000435",
    "role": "Deputy coordinator",
    "unitName": "Doctoral programme - Physics"},
   {"unitIdentifier": "STO0008627",
    "role": "Associate professor",
    "unitName": "Department of Physics"}]}]
```

Department names can be very long, so when you need to display them you can use the function this abbreviate.

NOTE: function is already fully implemented, do *not* modify it.

```
[3]: def abbreviate(unitName):

    abbreviations = {

        "Department of Psychology and Cognitive Science": "COGSCI",
        "Center for Mind/Brain Sciences - CIMeC": "CIMeC",
        "Department of Civil, Environmental and Mechanical Engineering": "DICAM",
        "Centre Agriculture Food Environment - C3A": "C3A",
        "School of International Studies - SIS": "SIS",
        "Department of Sociology and social research": "Sociology",
        "Faculty of Law": "Law",
        "Department of Economics and Management": "Economics",
        "Department of Information Engineering and Computer Science": "DISI",
        "Department of Cellular, Computational and Integrative Biology - CIBIO": "CIBIO"
    },
    "Department of Industrial Engineering": "DII"
}
if unitName in abbreviations:
    return abbreviations[unitName]
else:
    return unitName.replace("Department of ", "")
```

Example:

```
[4]: abbreviate("Department of Information Engineering and Computer Science")
[4]: 'DISI'
```

A1 calc_uid_to_abbr

⊕ It will be useful having a map from department ids to their abbreviations, if they are actually present, otherwise to their original name. To implement this, you can use the previously defined function abbreviate.

```
{
.
.
.
'STO0008629': 'DISI',
'STO0008630': 'Sociology',
'STO0008631': 'COGSCI',
.
.
.
'STO0012897': 'Institutional Relations and Strategic Documents',
.
.
}
```

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[5]: def calc_uid_to_abbr(db):

    ret = {}
    for person in db:
        for position in person['positions']:
            uid = position['unitIdentifier']
            ret[uid] = abbreviate(position['unitName'])
    return ret
```

```
#calc_uid_to_abbr(unitn)
print(calc_uid_to_abbr(unitn) ['STO0008629'])
print(calc_uid_to_abbr(unitn) ['STO0012897'])

DISI
Institutional Relations and Strategic Documents
```

```
</div>
```

```

A2.1 calc_prof_roles

⊗⊗ For each department, we want to see how many professor roles are covered, sorting them from greatest to lowest. In returned list we will only put the 10 department with most roles.

- **NOTE 1:** we are interested in *roles* covered. Don't care if actual people might be less (one person can cover more professor roles within the same unit)
- **NOTE 2:** there are several professor roles. Please avoid listing all roles in the code ("Senior Professor", "Visiting Professor",), and prefer using some smarter way to match them.

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[6]: def calc_prof_roles(db):
    hist = {}
    uid_to_abbr = calc_uid_to_abbr(db)

    for person in db:
        for position in person['positions']:
            role = position['role']
            uid = position['unitIdentifier']
            if 'professor'.lower() in role.lower():
                if uid in hist:
                    hist[uid] += 1
                else:
                    hist[uid] = 1

A3.1 calc_roles

⊕⊕ We want to calculate how many roles are covered for each department.

You will group roles by these macro groups (some already exist, some are new):

- Professor : “Senior Professor”, “Visiting Professor”, ...
- Research : “Senior researcher”, “Research collaborator”, ...
- Teaching : “Teaching assistant”, “Teaching fellow”, ...
- Guest : “Guest”, ...

and discard all the others (there are many, like “Rector”, “Head”, etc ..)

NOTE: Please avoid listing all roles in the code (“Senior researcher”, “Research collaborator”, ...), and prefer using some smarter way to match them.

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

[10]:

```
def calc_roles(db):

    ret = {}
    for person in db:
        for position in person['positions']:
            uid = position['unitIdentifier']
            role = position['role']
            grouped_role = None
            if "professor" in role.lower():
                grouped_role = 'Professor'
            elif "research" in role.lower():
                grouped_role = 'Research'
            elif "teaching" in role.lower():
                grouped_role = 'Teaching'
            elif "guest" in role.lower():
                grouped_role = 'Guest'

            if grouped_role:
                if uid in ret:
                    if grouped_role in ret[uid]:
                        ret[uid][grouped_role] += 1
                    else:
                        ret[uid][grouped_role] = 1
                else:
                    diz = {}

```
[12]: # EXPECTED RESULT
plot_roles(unitn, ['DISI', 'Sociology', 'COGSCI'])
```

A4.1 calc_shared

⊕⊕⊕ We want to calculate the 10 *department pairs* that have the greatest number of people working in *both* departments (regardless of role), sorted in decreasing order.

For example, ‘CIMeC’ and ‘COGSCI’ have 23 people working in both departments, meaning each of these 23 people has at least a position at CIMeC and at least a position at COGSCI.

NOTE: in this case we are looking at number of actual people, *not* number of roles covered

- we do not want to consider Doctoral programmes
- we do not want to consider ‘University of Trento’ department (STO0000001)
- if your calculations display with swapped names (‘COGSCI’, ‘CIMeC’, 23) instead of (‘CIMeC’, ‘COGSCI’, 23)
 -) it is not important, as long as they display just once per pair.

To implement this, we provide a sketch:

- build a dict which assigns unit codes to a set of *identifiers* of people that work for that unit
- to add elements to a set, use .add method
- to find common employees between two units, use set .intersection method (NOTE: it generates a *new* set)
- to check for all possible unit couples, you will need a double for on a list of departments. To avoid double checking pairs (so not have both (‘CIMeC’, ‘COGSCI’, 23) and (‘COGSCI’, ‘CIMeC’, 23) in output), you can think like you are visiting the lower of a matrix (for the sake of the example here we put only 4 departments with random numbers).

	0	1	2	3
0	DISI, COGSCI, CIMeC, DICAM	--	--	--
1	COGSCI	313	--	--
2	CIMeC	231	--	--
3	DICAM	12	13	123

Part B

B1 Theory

Write the solution in separate ``theory.txt`` file

Let M be a square matrix - a list containing n lists, each of them of size n. Return the computational complexity of function `fun()` with respect to n:

```
def fun(M):
    for row in M:
        for element in row:
            print(sum([x for x in row if x != element]))
```

Show answer<div class="jupman-sol jupman-sol-question" style="display:none">

ANSWER: $O(n^3)$

</div>

B2 Backpack

Open a text editor and edit file `backpack_sol.py`

We can model a backpack as stack of elements, each being a tuple with a name and a weight.

A sensible strategy to fill a backpack is to place heaviest elements to the bottom, so our backpack will allow pushing an element only if that element weight is equal or lesser than current topmost element weight.

The backpack has also a maximum weight: you can put any number of items you want, as long as its maximum weight is not exceeded.

Example

```
[17]: from backpack_sol import *
bp = Backpack(30) # max_weight = 30
bp.push('a', 10) # item 'a' with weight 10
DEBUG: Pushing (a,10)
```

```
[18]: print(bp)
Backpack: weight=10 max_weight=30
elements=[('a', 10)]
```

```
[19]: bp.push('b', 8)
DEBUG: Pushing (b,8)
```

```
[20]: print(bp)
Backpack: weight=18 max_weight=30
elements=[('a', 10), ('b', 8)]
```

```
>>> bp.push('c', 11)

DEBUG: Pushing (c,11)

ValueError: ('Pushing weight greater than top element weight! %s > %s', (11, 8))
```

```
[21]: bp.push('c', 7)

DEBUG: Pushing (c,7)
```

```
[22]: print(bp)

Backpack: weight=25 max_weight=30
          elements=[('a', 10), ('b', 8), ('c', 7)]
```

```
>>> bp.push('d', 6)

DEBUG: Pushing (d,6)

ValueError: Can't exceed max_weight ! (31 > 30)
```

B2.1 class

⊕⊕ Implement methods in the class Backpack, in the order they are shown. If you want, you can add debug prints by calling the `debug` function

IMPORTANT: the data structure should provide the total current weight in **O(1)**, so make sure to add and update an appropriate field to meet this constraint.

Testing: `python3 -m unittest backpack_test.BackpackTest`

B2.2 remove

⊕⊕ Implement function `remove`:

```
# NOTE: this function is implemented *outside* the class !

def remove(backpack, el):
    """
        Remove topmost occurrence of el found in the backpack,
        and RETURN it (as a tuple name, weight)

        - if el is not found, raises ValueError

        - DO *NOT* ACCESS DIRECTLY FIELDS OF BACKPACK !!!
          Instead, just call methods of the class!

        - MUST perform in O(n), where n is the backpack size

        - HINT: To remove el, you need to call Backpack.pop() until
              the top element is what you are looking for. You need
              to save somewhere the popped items except the one to
              remove, and then push them back again.

    """
```

Testing: python3 -m unittest backpack_test.RemoveTest

Example:

```
[23]: bp = Backpack(50)
```

```
bp.push('a', 9)
bp.push('b', 8)
bp.push('c', 8)
bp.push('b', 8)
bp.push('d', 7)
bp.push('e', 5)
bp.push('f', 2)

DEBUG: Pushing (a,9)
DEBUG: Pushing (b,8)
DEBUG: Pushing (c,8)
DEBUG: Pushing (b,8)
DEBUG: Pushing (d,7)
DEBUG: Pushing (e,5)
DEBUG: Pushing (f,2)
```

```
[24]: print(bp)
```

```
Backpack: weight=47 max_weight=50
          elements=[('a', 9), ('b', 8), ('c', 8), ('b', 8), ('d', 7), ('e', 5), ('f', 2)]
```

```
[25]: remove(bp, 'b')
```

```
DEBUG: Popping ('f', 2)
DEBUG: Popping ('e', 5)
DEBUG: Popping ('d', 7)
DEBUG: Popping ('b', 8)
DEBUG: Pushing (d,7)
DEBUG: Pushing (e,5)
DEBUG: Pushing (f,2)
```

```
[25]: ('b', 8)
```

```
[26]: print(bp)
```

```
Backpack: weight=39 max_weight=50
          elements=[('a', 9), ('b', 8), ('c', 8), ('d', 7), ('e', 5), ('f', 2)]
```

B.3 Concert

Start editing file `concert.py`.

When there are events with lots of potential visitors such as concerts, to speed up check-in there are at least two queues: one for cash where tickets are sold, and one for the actual entrance at the event.

Each visitor may or may not have a ticket. Also, since people usually attend in groups (couples, families, and so on), in the queue lines each group tends to move as a whole.

In Python, we will model a `Person` as a class you can create like this:

```
[27]: from concert_sol import *
```

```
[28]: Person('a', 'x', False)
[28]: Person(a,x,False)
```

a is the name, 'x' is the group, and False indicates the person doesn't have ticket

To model the two queues, in Concert class we have these fields and methods:

```
class Concert:

    def __init__(self):
        self._cash = deque()
        self._entrance = deque()

    def enqc(self, person):
        """ Enqueues at the cash from the right """
        self._cash.append(person)

    def enqe(self, person):
        """ Enqueues at the entrance from the right """
        self._entrance.append(person)
```

B3.1 dequeue

⊕⊕⊕ Implement dequeue. If you want, you can add debug prints by calling the debug function.

```
def dequeue(self):
    """ RETURN the names of people admitted to concert

    Dequeuing for the whole queue system is done in groups, that is,
    with a _single_ call to dequeue, these steps happen, in order:
    1. entrance queue: all people belonging to the same group at
       the front of entrance queue who have the ticket exit the queue
       and are admitted to concert. People in the group without the
       ticket are sent to cash.
    2. cash queue: all people belonging to the same group at the front
       of cash queue are given a ticket, and are queued at the entrance queue
    """

```

Testing: python3 -m unittest concert_test.DequeueTest

Example:

```
[29]: con = Concert()

con.enqc(Person('a','x',False)) # a,b,c belong to same group x
con.enqc(Person('b','x',False))
con.enqc(Person('c','x',False))
con.enqc(Person('d','y',False)) # d belongs to group y
con.enqc(Person('e','z',False)) # e,f belongs to group z
con.enqc(Person('f','z',False))
con.enqc(Person('g','w',False)) # g belongs to group w
```

```
[30]: con

[30]: Concert:
       cash: deque([Person(a,x,False),
                    Person(b,x,False),
                    Person(c,x,False),
                    Person(d,y,False),
                    Person(e,z,False),
                    Person(f,z,False),
                    Person(g,w,False)])
       entrance: deque([])
```

First time we dequeue, entrance queue is empty so no one enters concert, while at the cash queue people in group x are given a ticket and enqueued at the entrance queue

NOTE: The messages on the console are just debug print, the function `dequeue` only return name of people admitted to concert

```
[31]: con.dequeue()

Special dequeue case: broken group

In the special case when there is a group at the entrance with one or more members without a ticket, it is assumed that the group gets broken, so whoever has the ticket enters and the others get enqueued at the cash.

```

2.1.10 Midterm - Thu 07, Nov 2019

Scientific Programming - Data Science @ University of Trento

Download exercises and solution

Introduction

- Taking part to this exam erases any vote you had before

⁸⁹ <https://en.softpython.org/pandas/eures-jobs-sol.html>

Grading

- **Correct implementations:** Correct implementations with the required complexity grant you full grade.
- **Partial implementations:** Partial implementations *might* still give you a few points. If you just can't solve an exercise, try to solve it at least for some subcase (i.e. array of fixed size 2) commenting why you did so.
- **Bonus point:** One bonus point can be earned by writing stylish code. You got style if you:
 - do not infringe the [Commandments](#)⁹⁰
 - write [pythonic code](#)⁹¹
 - avoid convoluted code like i.e.

```
if x > 5:
    return True
else:
    return False
```

when you could write just

```
return x > 5
```

Valid code

WARNING: MAKE SURE ALL EXERCISE FILES AT LEAST COMPILE !!! 10 MINS BEFORE THE END OF THE EXAM I WILL ASK YOU TO DO A FINAL CLEAN UP OF THE CODE

WARNING: ONLY IMPLEMENTATIONS OF THE PROVIDED FUNCTION SIGNATURES WILL BE EVALUATED !!!!!!!!

For example, if you are given to implement:

```
def f(x):
    raise Exception("TODO implement me")
```

and you ship this code:

```
def my_f(x):
    # a super fast, correct and stylish implementation

def f(x):
    raise Exception("TODO implement me")
```

We will assess only the latter one `f(x)`, and conclude it doesn't work at all :P !!!!!!!

Helper functions

Still, you are allowed to define any extra helper function you might need. If your `f(x)` implementation calls some other function you defined like `my_f` here, it is ok:

⁹⁰ <https://sciprog.davidleoni.it/commandments.html>

⁹¹ <http://docs.python-guide.org/writing/style>

```
# Not called by f, will get ignored:  
def my_g(x):  
    # bla  
  
# Called by f, will be graded:  
def my_f(y,z):  
    # bla  
  
def f(x):  
    my_f(x, 5)
```

How to edit and run

To edit the files, you can use any editor of your choice, you can find them under *Applications->Programming*:

- **Visual Studio Code**
- Editra is easy to use, you can find it under *Applications->Programming->Editra*.
- Others could be *GEdit* (simpler), or *PyCharm* (more complex).

To run the tests, use **the Terminal** which can be found in *Accessories -> Terminal*

IMPORTANT: Pay close attention to the comments of the functions.

WARNING: *DON'T* modify function signatures! Just provide the implementation.

WARNING: *DON'T* change the existing test methods, just add new ones !!! You can add as many as you want.

WARNING: *DON'T* create other files. If you still do it, they won't be evaluated.

Debugging

If you need to print some debugging information, you are allowed to put extra print statements in the function bodies.

WARNING: even if print statements are allowed, be careful with prints that might break your function!

For example, avoid stuff like this:

```
x = 0  
print(1/x)
```

What to do

- 1) Download `sciprog-ds-2019-11-07-exam.zip` and extract it on your desktop. Folder content should be like this:

```
sciprog-ds-2019-11-07-FIRSTNAME-LASTNAME-ID
    jupman.py
    sciprog.py
    exam-2019-11-07.ipynb
```

- 2) Rename `sciprog-ds-2019-11-07-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2019-11-07-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins. If it takes longer, leave it and try another exercise.
- 4) When done:
 - if you have unitn login: zip and send to examina.icts.unitn.it/studente⁹²
 - If you don't have unitn login: tell instructors and we will download your work manually

Part A

Open Jupyter and start editing this notebook `exam-2019-11-07.ipynb`

You will work on a dataset of events which occur in the Municipality of Trento, in years 2019-20. Each event can be held during a particular day, two days, or many specified as a range. Events are written using natural language, so we will try to extract such dates, taking into account that information sometimes can be partial or absent.

Data provider: [Comune di Trento](#)⁹³

License: [Creative Commons Attribution 4.0](#)⁹⁴

WARNING: avoid constants in function bodies !!

In the exercises data you will find many names and connectives such as 'Giovedì', 'Novembre', 'e', 'a', etc. DO NOT put such constant names inside body of functions !! You have to write generic code which works with any input.

```
[2]: import pandas as pd      # we import pandas and for ease we rename it to 'pd'
import numpy as np        # we import numpy and for ease we rename it to 'np'

# remember the encoding !
eventi = pd.read_csv('data/eventi.csv', encoding='UTF-8')
eventi.info()

<class 'pandas.core.frame.DataFrame'>
RangeIndex: 253 entries, 0 to 252

```

A.1 leap_year

⊕ A leap year has 366 days instead of regular 365. You are given some criteria to detect whether or not a year is a leap year. Implement them in a function which given a year as a number RETURN `True` if it is a leap year, `False` otherwise.

IMPORTANT: in Python there are predefined methods to detect leap years, but here you **MUST write your own code!**

1. If the year is evenly divisible by 4, go to step 2. Otherwise, go to step 5.
2. If the year is evenly divisible by 100, go to step 3. Otherwise, go to step 4.
3. If the year is evenly divisible by 400, go to step 4. Otherwise, go to step 5.
4. The year is a leap year (it has 366 days)
5. The year is not a leap year (it has 365 days)

(if you're curious about calendars, see [this link](#)⁹⁵)

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

[4]: `def is_leap(year):`

```

    if year % 4 == 0:
        if year % 100 == 0:
            return year % 400 == 0
        else:
            return True
    else:
        return False

assert is_leap(2600)    == False
```

A.2 full_date

⊕⊕ Write function `full_date` which takes some natural language text representing a complete date and outputs a string in the format `yyyy-mm-dd` like `2019-03-25`.

- Dates will be expressed in Italian, so we report here the corresponding translations
- your function should work regardless of capitalization of input
- we assume the date to be always well formed

Examples:

At the beginning you always have day name (Mercoledì means *Wednesday*):

```
>>> full_date("Mercoledì 13 Novembre 2019")
"2019-11-13"
```

Right after day name, you *may* also find a day phase, like mattina for morning:

```
>>> full_date("Mercoledì mattina 13 Novembre 2019")
"2019-11-13"
```

Remember you can have lowercases and single digits which must be prepended by zero:

```
>>> full_date("domenica 4 dicembre 1923")
"1923-12-04"
```

For more examples, see assertions.

```
[5]: days = ['lunedì', 'martedì', 'mercoledì', 'giovedì', 'venerdì', 'sabato', 'domenica']

months = ['gennaio', 'febbraio', 'marzo', 'aprile', 'maggio', 'giugno',
          'luglio', 'agosto', 'settembre', 'ottobre', 'novembre', 'dicembre']

#           morning,    afternoon,   evening, night
day_phase = ['mattina', 'pomeriggio', 'sera', 'notte']
```

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[6]: def full_date(text):

    ntext = text.lower()
    words = ntext.split()
    i = 1
    if words[i] in day_phase:
        i += 1
    day = int(words[i])
    i += 1

    month = int(months.index(words[i])) + 1
    i += 1

    year = int(words[i])

    return "{:04d}-{:02d}-{:02d}".format(year, month, day)
```

```
assert full_date("Giovedì 14 novembre 2019") == "2019-11-14"
assert full_date("Giovedì 7 novembre 2019") == "2019-11-07"
assert full_date("Giovedì pomeriggio 14 novembre 2019") == "2019-11-14"
assert full_date("sabato mattina 25 marzo 2017") == "2017-03-25"
assert full_date("Mercoledì 13 Novembre 2019") == "2019-11-13"
assert full_date("domenica 4 dicembre 1923") == "1923-12-04"
```

</div>

```
[6]: def full_date(text):
    raise Exception('TODO IMPLEMENT ME !')

assert full_date("Giovedì 14 novembre 2019") == "2019-11-14"
assert full_date("Giovedì 7 novembre 2019") == "2019-11-07"
assert full_date("Giovedì pomeriggio 14 novembre 2019") == "2019-11-14"
assert full_date("sabato mattina 25 marzo 2017") == "2017-03-25"
assert full_date("Mercoledì 13 Novembre 2019") == "2019-11-13"
assert full_date("domenica 4 dicembre 1923") == "1923-12-04"
```

A.3 partial_date

⊕⊕⊕ Write a function `partial_date` which takes a natural language text representing one or more dates, and RETURN only the FIRST date found, in the format `yyyy-mm-dd`. If the FIRST date contains insufficient information to form a complete date, in the returned date leave the characters '`yyyy`' for unknown year, '`mm`' for unknown months and '`dd`' for unknown day.

NOTE: Here we only care about FIRST date, **DO NOT** attempt to fetch eventual missing information from the second date, we will deal with that in a later exercise.

Examples:

```
>>> partial_date("Giovedì 7 novembre 2019")
"2019-11-07"

>>> partial_date("venerdì 15 novembre")
"yyyy-11-15"

>>> partial_date("venerdì pomeriggio 15 e sabato mattina 16 novembre 2019")
"yyyy-mm-15"
```

For more examples, see asserts.

```
[7]: connective_and = 'e'

connective_from = 'da'
connective_to = 'a'

days = ['lunedì', 'martedì', 'mercoledì', 'giovedì', 'venerdì', 'sabato', 'domenica']
months = ['gennaio', 'febbraio', 'marzo', 'aprile', 'maggio', 'giugno',
          'luglio', 'agosto', 'settembre', 'ottobre', 'novembre', 'dicembre']

# morning, afternoon, evening, night
day_phases = ['mattina', 'pomeriggio', 'sera', 'notte']
```

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[8]: def partial_date(text):

    if type(text) != str:
        return 'yyyy-mm-dd'

    year = 'yyyy'
    month = 'mm'
    day = 'dd'

    ntext = text.lower()
    ret = []
    words = ntext.split()

    if len(words) > 0:
        if words[0] == connective_from:
            i = 1
        else:
            i = 0
        if words[i] in days:
            i = i + 1
```

(continues on next page)

(continued from previous page)

```

if words[i] in day_phases:
    i += 1
day = "{:02d}".format(int(words[i]))
i += 1
if i < len(words):
    # 'e' case with double date
    if words[i] in months:
        month = "{:02d}".format(months.index(words[i]) + 1)
        i += 1
    if i < len(words):
        if words[i].isdigit():
            year = "{:04d}".format(int(words[i]))

return "%s-%s-%s" % (year, month, day)

# complete, uppercase day
assert partial_date("Giovedì 7 novembre 2019") == "2019-11-07"
assert partial_date("Giovedì 14 novembre 2019") == "2019-11-14"
# lowercase day
assert partial_date("mercoledì 13 novembre 2019") == "2019-11-13"
# lowercase, dayphase, missing month and year
assert partial_date("venerdì pomeriggio 15") == "yyyy-mm-15"
# single day, lowercase, no year
assert partial_date("venerdì 15 novembre") == "yyyy-11-15"

    25"
assert partial_date("da giovedì 12 a domenica 15 dicembre 2019") == "yyyy-mm-12"
assert partial_date("da giovedì 9 a domenica 12 gennaio 2020") == "yyyy-mm-09"
assert partial_date("Da lunedì 04 a domenica 10 novembre 2019") == "yyyy-mm-04"

```

</div>

```
[8]: def partial_date(text):
    raise Exception('TODO IMPLEMENT ME !')

# complete, uppercase day
assert partial_date("Giovedì 7 novembre 2019") == "2019-11-07"
assert partial_date("Giovedì 14 novembre 2019") == "2019-11-14"
# lowercase day
assert partial_date("mercoledì 13 novembre 2019") == "2019-11-13"
# lowercase, dayphase, missing month and year
assert partial_date("venerdì pomeriggio 15") == "yyyy-mm-15"
# single day, lowercase, no year
assert partial_date("venerdì 15 novembre") == "yyyy-11-15"
```

(continues on next page)

(continued from previous page)

```
# no year, hour / location to be discarded
assert partial_date("venerdì 5 aprile alle 20:30 in via degli Olmi 26 (Trento sud)") \
    == "yyyy-04-05"

# two dates, 'and' connective ('e'), day phase morning/afternoon ('mattina'/
# → 'pomeriggio')
assert partial_date("venerdì pomeriggio 15 e sabato mattina 16 novembre 2019") \
    == "yyyy-mm-15"

# two dates, begins with connective 'Da'
assert partial_date("Da lunedì 25 novembre a domenica 01 dicembre 2019") == "yyyy-11-"
# → 25"
assert partial_date("da giovedì 12 a domenica 15 dicembre 2019") == "yyyy-mm-12"
assert partial_date("da giovedì 9 a domenica 12 gennaio 2020") == "yyyy-mm-09"
assert partial_date("Da lunedì 04 a domenica 10 novembre 2019") == "yyyy-mm-04"
```

A.4 parse_dates_and

⊕⊕⊕ Write a function which, given a string representing two possibly partial dates separated by the `e` connective (*and*), RETURN a tuple holding the two extracted dates each in the format `yyyy-mm-dd`.

- **IMPORTANT:** Notice that the year or month of the first date might actually be indicated in the second date ! In this exercise we want missing information in the first date to be filled in with year and/or month taken from second date.
- **HINT:** implement this function calling previously defined functions. If you do so, it will be fairly easy.

Examples:

```
>>> parse_dates_and("venerdì pomeriggio 15 e sabato mattina 16 novembre 2019")
("2019-11-15", "2019-11-16")

>>> parse_dates_and("lunedì 4 e domenica 10 novembre")
("yyyy-11-04", "yyyy-11-10")
```

For more examples, see asserts.

[Show solution](#) data-jupman-show="Show solution" data-jupman-hide="Hide"

[9]:

```
def parse_dates_and(text):

    ntext = text.lower()

    strings = ntext.split(' ' + connective_and + ' ')
    date_left = partial_date(strings[0])
    date_right = partial_date(strings[1])
    if 'yyyy' in date_left:
        date_left = date_left.replace('yyyy', date_right[0:4])
    if 'mm' in date_left:
        date_left = date_left.replace('mm', date_right[5:7])
    return (date_left, date_right)
```

(continues on next page)

(continued from previous page)

```

# complete dates

```

A.5 Fake news generator

Functional illiteracy⁹⁶ is reading and writing skills that are inadequate “to manage daily living and employment tasks that require reading skills beyond a basic level”

⊕⊕ Knowing that functional illiteracy is on the rise, a news website wants to fire obsolete human journalists and attract customers by feeding them with automatically generated *fake news*. You are asked to develop the algorithm for producing the texts: while ethically questionable, the company pays well, so you accept.

Typically, a *fake news* starts with a real subject, a real fact (the *antecedent*), and follows it with some invented statement (the *consequence*). You are provided by the company three databases, one with subjects, one with antecedents and one of consequences. To each antecedent and consequence is associated a topic.

Write a function `fake_news` which takes the databases and RETURN a list holding strings with all possible combinations of subjects, antecedents and consequences where the topic of antecedent matches the one of consequence. See desired output for more info.

NOTE: Your code MUST work with *any* database

2.1.11 Midterm B - Fri 20, Dec 2019

Scientific Programming - Data Science @ University of Trento

Download exercises and solution

Introduction

You can take this midterm ONLY IF you got grade ≥ 16 in Part A midterm.

What to do

- 1) Download `sciprog-ds-2019-12-20-exam.zip` and extract it on your desktop. Folder content should be like this:

```
sciprog-ds-2019-12-20-FIRSTNAME-LASTNAME-ID
  exam-2019-12-20.ipynb
  theory.txt
  linked_list.py
  linked_list_test.py
  bin_tree.py
  bin_tree_test.py
  jupman.py
  sciprog.py
```

- 2) Rename `sciprog-ds-2019-12-20-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2019-12-20-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins.
If it takes longer, leave it and try another exercise.
- 4) When done:
 - if you have unitn login: zip and send to examina.icts.unitn.it/studente⁹⁷
 - If you don't have unitn login: tell instructors and we will download your work manually

Part B

B1 Theory

Write the solution in separate ``theory.txt`` file

⁹⁷ <http://examina.icts.unitn.it/studente>

B1.1 Complexity

Given a list L of n elements, please compute the asymptotic computational complexity of the following function, explaining your reasoning.

```
def my_fun(L):
    R = 0
    for i in range(len(L)):
        for j in range(len(L)-1, 0, -1):
            k = 0
            while k < 4:
                R = R + L[j] - L[i]
                k += 1
    return R
```

B1.2 Data structure choice

Given an algorithm that frequently checks the presence of an element in its internal data structure. Please briefly answer the following questions:

- What data structure would you choose? Why?
- In case entries are sorted, would you use the same data structures?

B2 LinkedList

Open a text editor and edit file linkedlist.py

You are given a `LinkedList` holding pointers `_head`, `_last`, and also `_size` attribute.

Notice the list also holds `_last` and `_size` attributes !!!

B2.1 rotate

⊕⊕ Implement this method:

```
def rotate(self):
    """ Rotate the list of 1 element, that is, removes last node and
    inserts it as the first one.

    - MUST execute in O(n) where n is the length of the list
    - Remember to also update _last pointer
    - WARNING: DO *NOT* try to convert whole linked list to a python list
    - WARNING: DO *NOT* swap node data or create nodes, I want you to
              change existing node links !!
    """

```

Testing: `python3 -m unittest linked_list_test.RotateTest`

Example:

```
[2]: from linked_list_sol import *
```

[3]:

```
ll = LinkedList()
ll.add('d')
ll.add('c')
ll.add('b')
ll.add('a')
print(ll)
```

LinkedList: a,b,c,d

[4]: ll.rotate()

[5]: print(ll)

LinkedList: d,a,b,c

B2.2 rotaten

⊕⊕⊕ Implement this method:

```
def rotaten(self, k):
    """ Rotate k times the linkedlist

        - k can range from 0 to any positive integer number (even greater than list_size)
        - if k < 0 raise ValueError

        - MUST execute in O( n-(k%n) ) where n is the length of the list
        - WARNING: DO *NOT* call .rotate() k times !!!! 
        - WARNING: DO *NOT* try to convert whole linked list to a python list
        - WARNING: DO *NOT* swap node data or create nodes, I want you to
                  change node links !!
    """

```

Testing: python3 -m unittest linked_list_test.RotatenTest

IMPORTANT HINT

The line “MUST execute in $O(n-(k \% n))$ where n is the length of the list” means that you have to calculate $m = k \% n$, and then only scan first $n-m$ nodes!

Example:

[6]:

```
ll = LinkedList()
ll.add('h')
ll.add('g')
ll.add('f')
ll.add('e')
ll.add('d')
ll.add('c')
ll.add('b')
ll.add('a')
print(ll)
```

```
LinkedList: a,b,c,d,e,f,g,h
```

```
[7]: ll.rotaten(0) # changes nothing
```

```
[8]: print(ll)
```

```
LinkedList: a,b,c,d,e,f,g,h
```

```
[9]: ll.rotaten(3)
```

```
[10]: print(ll)
```

```
LinkedList: f,g,h,a,b,c,d,e
```

```
[11]: ll.rotaten(8) # changes nothing
```

```
[12]: print(ll)
```

```
LinkedList: f,g,h,a,b,c,d,e
```

```
[13]: ll.rotaten(5)
```

```
[14]: print(ll)
```

```
LinkedList: a,b,c,d,e,f,g,h
```

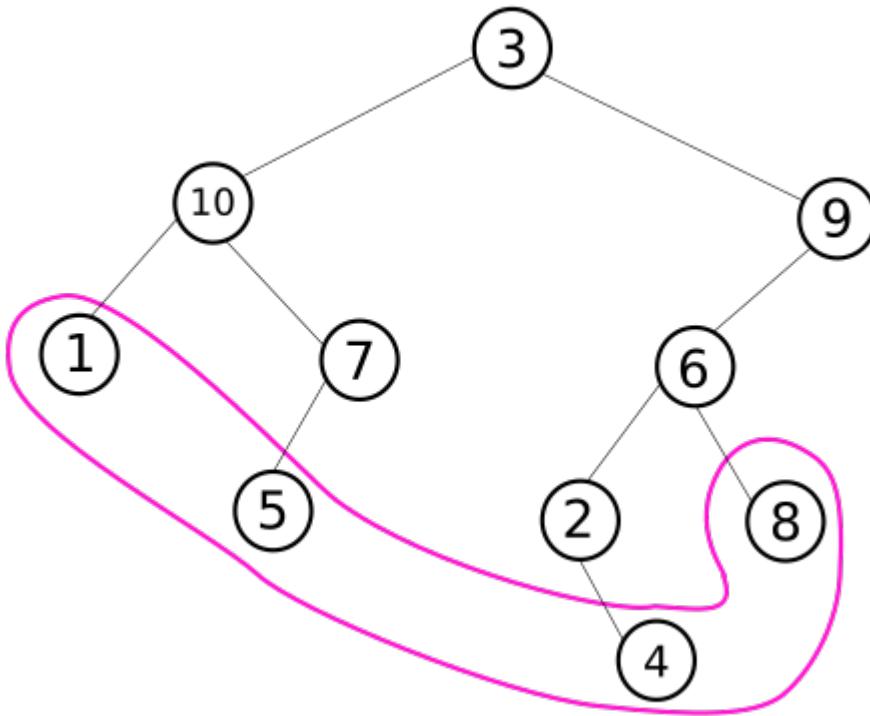

```
[15]: ll.rotaten(11) # 11 = 8 + 3 , only rotates 3 nodes
```

```
[16]: print(ll)
```

```
LinkedList: f,g,h,a,b,c,d,e
```

B3 Binary trees

We will now go looking for leaves, that is, nodes with no children. Open `bin_tree`.

```
[17]: from bin_tree_test import bt
      from bin_tree_sol import *
```

B3.1 sum_leaves_rec

⊕⊕ Implement this method:

```
def sum_leaves_rec(self):
    """ Supposing the tree holds integer numbers in all nodes,
        RETURN the sum of ONLY the numbers in the leaves.

        - a root with no children is considered a leaf
        - implement it as a recursive Depth First Search (DFS) traversal
          NOTE: with big trees a recursive solution would surely
                exceed the call stack, but here we don't mind
    """

```

Testing: python3 -m unittest bin_tree_test.SumLeavesRecTest

Example:

```
[18]: t = bt(3,
           bt(10,
               bt(1),
               bt(7,
                   bt(5))),
           bt(9,
```

(continues on next page)

(continued from previous page)

```
bt(6,
    bt(2,
        None,
        bt(4)),
    bt(8)))))

t.sum_leaves_rec() # 1 + 5 + 4 + 8
```

[18]: 18

B3.2 leaves_stack

⊕⊕⊕ Implement this method:

```
def leaves_stack(self):
    """ RETURN a list holding the *data* of all the leaves of the tree,
    in left to right order.

    - a root with no children is considered a leaf
    - DO *NOT* use recursion
    - implement it with a while and a stack (as a Python list)
    """

```

Testing: python3 -m unittest bin_tree_test.LeavesStackTest

Example:

```
[19]: t = bt('a',
    bt('b',
        bt('c'),
        bt('d',
            None,
            bt('e'))),
    bt('f',
        bt('g',
            bt('h')),
        bt('i'))))
t.leaves_stack()
```

[19]: ['c', 'e', 'h', 'i']

[]:

```
[1]: # Please execute this cell
import sciprog
```

2.1.12 Exam - Thu 23, Jan 2020

Scientific Programming - Data Science @ University of Trento

Download exercises and solution

Introduction

- **Taking part to this exam erases any vote you had before**

What to do

- 1) Download `sciprog-ds-2020-01-23-exam.zip` and extract it on your desktop. Folder content should be like this:

```
sciprog-ds-2020-01-23-FIRSTNAME-LASTNAME-ID
  data
    db.mm
    proof.txt

  exam-2020-01-23.ipynb
  digi_list.py
  digi_list_test.py
  bin_tree.py
  bin_tree_test.py
  jupman.py
  sciprog.py
```

- 2) Rename `sciprog-ds-2020-01-23-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2020-01-23-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins. If it takes longer, leave it and try another exercise.
- 4) When done:
 - if you have unitn login: zip and send to examina.icts.unitn.it/studente⁹⁸
 - If you don't have unitn login: tell instructors and we will download your work manually

Part A

Open Jupyter and start editing this notebook `exam-2020-01-23.ipynb`

⁹⁸ <http://examina.icts.unitn.it/studente>

Metamath

Metamath⁹⁹ is a language that can express theorems, accompanied by proofs that can be verified by a computer program. Its website lets you browse from complex theorems¹⁰⁰ up to the most basic axioms¹⁰¹ they rely on to be proven .

For this exercise, we have two files to consider, db.mm and proof.txt.

- db.mm contains the description of a simple algebra where you can only add zero to variables
- proof.txt contains the awesome proof that... any variable is equal to itself

The purpose of this exercise is to visualize the steps of the proof as a graph, and visualize statement frequencies.

DISCLAIMER: No panic !

You **DO NOT** need to understand *any* of the mathematics which follows. Here we are *only* interested in parsing the data and visualize it

Metamath db

First you will load data/db.mm and parse text file into Python, here is the full content:

```
$ ( Declare the constant symbols we will use $)
    $c 0 + = -> ( ) term wff |- $.
$( Declare the metavariables we will use $)
    $v t r s P Q $.
$( Specify properties of the metavariables $)
    tt $f term t $.
    tr $f term r $.
    ts $f term s $.
    wp $f wff P $.
    wq $f wff Q $.
$( Define "term" and "wff" $)
    tze $a term 0 $.
    tpl $a term ( t + r ) $.
    weq $a wff t = r $.
    wim $a wff ( P -> Q ) $.
$( State the axioms $)
    a1 $a |- ( t = r -> ( t = s -> r = s ) ) $.
    a2 $a |- ( t + 0 ) = t $.
$( Define the modus ponens inference rule $)
    ${
        min $e |- P $.
        maj $e |- ( P -> Q ) $.
        mp $a |- Q $.
    }
```

Format description:

- Each row is a *statement*
- Words are separated by spaces. Each word that appears in a *statement* is called a *token*
- Tokens starting with dollar \$ are called *keywords*, you may have \$ (, \$) , \$c, \$v, \$a,\$f,\${,\$}, \$.

⁹⁹ <http://us.metamath.org>

¹⁰⁰ http://us.metamath.org/mm_100.html

¹⁰¹ <http://us.metamath.org/mpeuni/mmtheorems1.html#mm5s>

- Statements *may* be identified with a unique arbitrary *label*, which is placed at the beginning of the row. For example, tt, weq, maj are all labels (in the file there are more):

```
- tt $f term t $.
- weq $a wff t = r $.
- maj $e |- ( P -> Q ) $.
```

- Some rows have no label, examples:

```
- $c 0 + = -> ( ) term wff |- $.
- $v t r s P Q $.
- $( State the axioms $)
- ${
- }
```

- in each row, after the first dollar *keyword*, you *may* have an arbitrary *sequence* of characters terminated by a dollar followed by a dot \$. **You don't need to care about the sequence meaning!** Examples:

```
- tt $f term t $. has sequence term t
- weq $a wff t = r $. has sequence wff t = r
- $v t r s P Q $. has sequence t r s P Q
```

Now implement function `parse_db` which scans the file line by line (it is a text file, so you can use [line files examples](#)¹⁰²), parses ONLY rows with labels, and RETURN a dictionary mapping labels to remaining data in the row represented as a dictionary, formatted like this (showing here only first three labels):

```
{
  'a1': { 'keyword': '$a',
           'sequence': '|- ( t = r -> ( t = s -> r = s ) )' },
  'a2': {
           'keyword': '$a',
           'sequence': '|- ( t + 0 ) = t' },
  'maj': {
           'keyword': '$e',
           'sequence': '|- ( P -> Q )' },
  .
  .
  .
}
```

¹⁰² <https://sciprog.davidleoni.it/formats/format-sol.html#1.-line-files>

A.1 Metamath db

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

data-jupman-show="Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[2]: def parse_db(filepath):

    ret = {}
    with open(filepath, encoding='utf-8') as f:
        line=f.readline().strip()
        while line != "":
            #print(line)

            if line.startswith('${'):
                label = ''
                keyword = '${'
                sequence = ''
            elif line.split()[0].startswith('${'):
                label = ''
                keyword = '${'
                sequence = ''
            elif line.split()[0].startswith('${}'):
                label = ''
                keyword = '${}'
                sequence = ''

A.2 Metamath proof

A proof file is made of steps, one per row. Each statement, in order to be proven, needs other steps to be proven until very basic facts called axioms are reached, which need no further proof (typically proofs in Metamath are shown in much shorter format, but here we use a more explicit way)

So a proof can be nicely displayed as a tree of the steps it is made of, where the top node is the step to be proven and the axioms are the leaves of the tree.

Complete content of data/proof.txt:

```
1 tt      $f term t
2 tze     $a term 0
3 1,2 tpl $a term ( t + 0 )
4 tt      $f term t
5 3,4 weq $a wff ( t + 0 ) = t
6 tt      $f term t
7 tt      $f term t
8 6,7 weq $a wff t = t
9 tt      $f term t
```

(continues on next page)

(continued from previous page)

```

10 9 a2      $a |- ( t + 0 ) = t
11 tt        $f term t
12 tze       $a term 0
13 11,12 tpl $a term ( t + 0 )
14 tt        $f term t
15 13,14 weq $a wff ( t + 0 ) = t
16 tt        $f term t
17 tze       $a term 0
18 16,17 tpl $a term ( t + 0 )
19 tt        $f term t
20 18,19 weq $a wff ( t + 0 ) = t
21 tt        $f term t
22 tt        $f term t
23 21,22 weq $a wff t = t
24 20,23 wim $a wff ( ( t + 0 ) = t -> t = t )
25 tt        $f term t
26 25 a2      $a |- ( t + 0 ) = t
27 tt        $f term t
28 tze       $a term 0

33 15,24,26,32 mp  $a |- ( ( t + 0 ) = t -> t = t )
34 5,8,10,33 mp  $a |- t = t

```

Each line represents a step of the proof. Last line is the final goal of the proof.

Each line contains, in order:

- a step number at the beginning, starting from 1 (step_id)
- possibly a list of other step_ids, separated by commas, like 29, 30, 31 - they are references to previous rows
- label of the db_mm statement referenced by the step, like tt, tze, weq - that label must have been defined somewhere in db.mm file
- statement type: a token starting with a dollar, like \$a, \$f
- a sequence of characters, like (for you they are just characters, **don't care about the meaning !**):
 - term (t + 0)
 - |- ((t + 0) = t -> ((t + 0) = t -> t = t))

Implement function `parse_proof`, which takes a `filepath` to the proof and RETURN a list of steps expressed as a dictionary, in this format (showing here only first 5 items):

NOTE: referenced `step_ids` are **integer** numbers and they are the original ones from the file, meaning they start **from one**.

```

Checking proof

If you've done everything properly, by executing following cells you should be able to see nice graphs.

IMPORTANT: You do not need to implement anything!

Just look if results match expected graphs

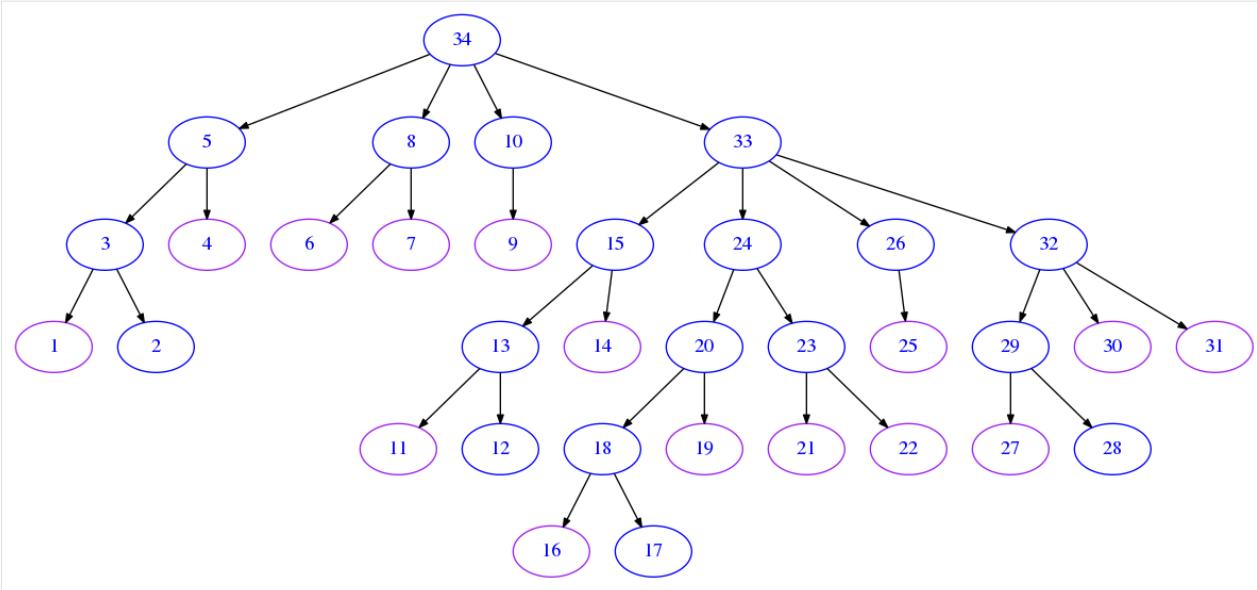

Overview plot

Here we only show step numbers using function `draw_proof` defined in `sciprog` library

```
[5]: from sciprog import draw_proof
# uncomment and check
#draw_proof(proof, db_mm, only_ids=True) # all graph, only numbers
```

```
[6]: print()
print('***** EXPECTED COMPLETE GRAPH *****')
draw_proof(proof, db_mm, only_ids=True)
```

```
***** EXPECTED COMPLETE GRAPH *****
```

Detail plot

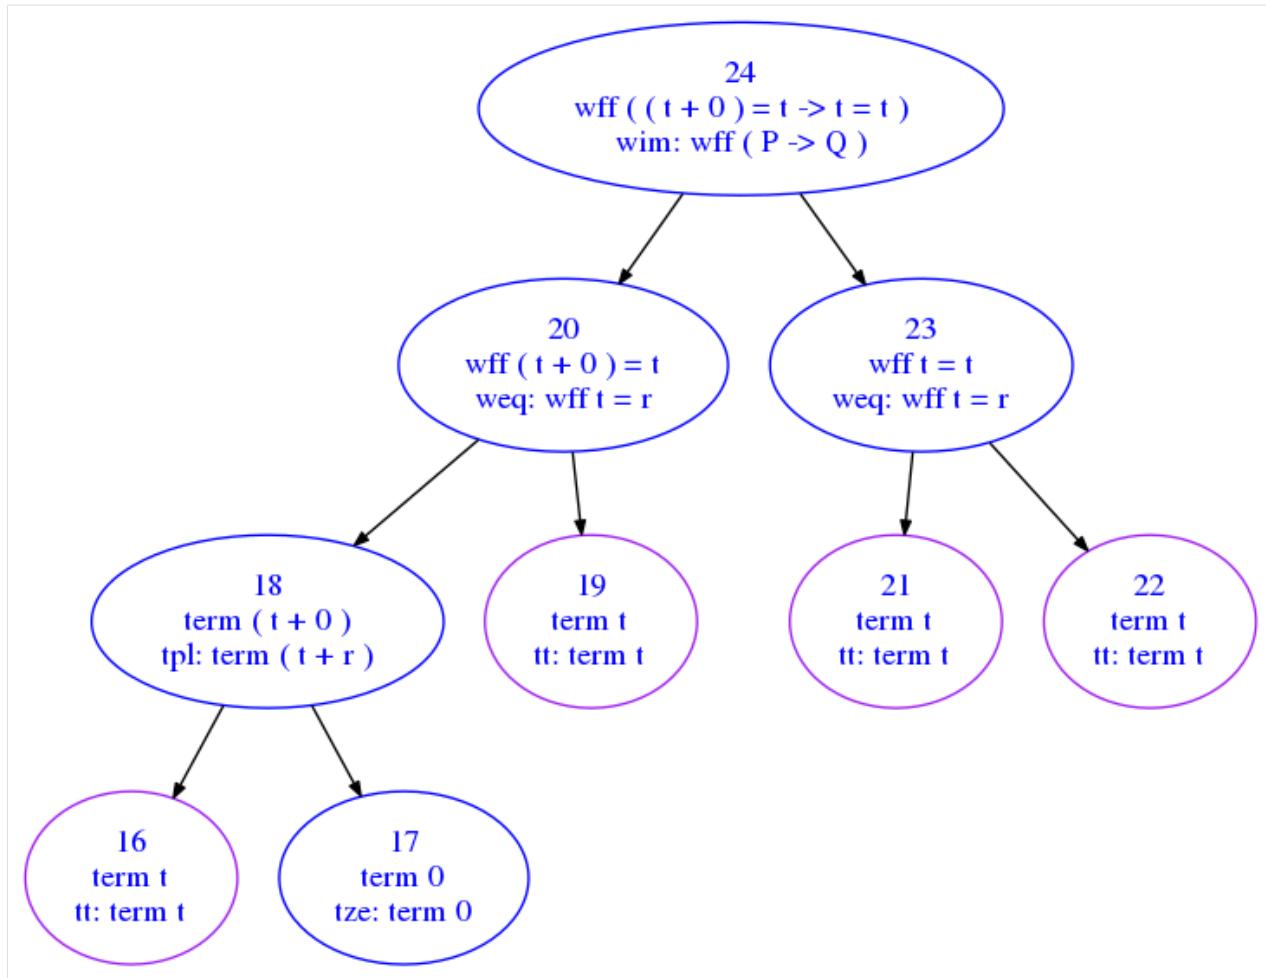

Here we show data from both the `proof` and the `db_mm` we calculated earlier. To avoid having a huge graph we only focus on subtree starting from `step_id=24`.

To understand what is shown, look at node 20: - first line contains statement `wff (t + 0) = t` taken from line 20 of `proof` file - second line `weq: wff t = r` is taken from `db_mm`, and means rule labeled `weq` was used to derive the statement in the first line.

```
[7]: # uncomment and check
#draw_proof(proof, db_mm, step_id=24)
```

```
[8]: print()
print('***** EXPECTED DETAIL GRAPH ****')
print('*****')
draw_proof(proof, db_mm, step_id=24)
```

```
***** EXPECTED DETAIL GRAPH *****
```

A.3 Metamath top statements

We can measure the importance of theorems and definitions (in general, *statements*) by counting how many times they are referenced in proofs.

A3.1 histogram

Write some code to plot the histogram of *statement* labels referenced by steps in `proof`, from most to least frequently referenced.

A label gets a count each time a step references another step with that label.

For example, in the subgraph above:

- `tt` is referenced 4 times, that is, there are 4 steps referencing other steps which contain the label `tt`
- `weq` is referenced 2 times
- `tpl` and `tze` are referenced 1 time each
- `wim` is referenced 0 times (it is only present in the last node, which being the root node cannot be referenced by any step)

NOTE: the previous counts are just for the subgraph example.

In your exercise, you will need to consider all the steps

A3.2 print list

Below the graph, print the list of labels from most to least frequent, associating them to corresponding statement sequence taken from db_mm

[9]: # write here

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

[10]:

```
# SOLUTION

import numpy as np
import matplotlib.pyplot as plt

freqs = {}
for step in proof:
    for step_id in step['step_ids']:
        label = proof[step_id-1]['label']
        if label not in freqs:
            freqs[label] = 1
        else:
            freqs[label] += 1

xs = np.arange(len(freqs.keys()))

coords = [(k, freqs[k]) for k in freqs]

coords.sort(key=lambda c: c[1], reverse=True)

ys_in = [c[1] for c in coords]

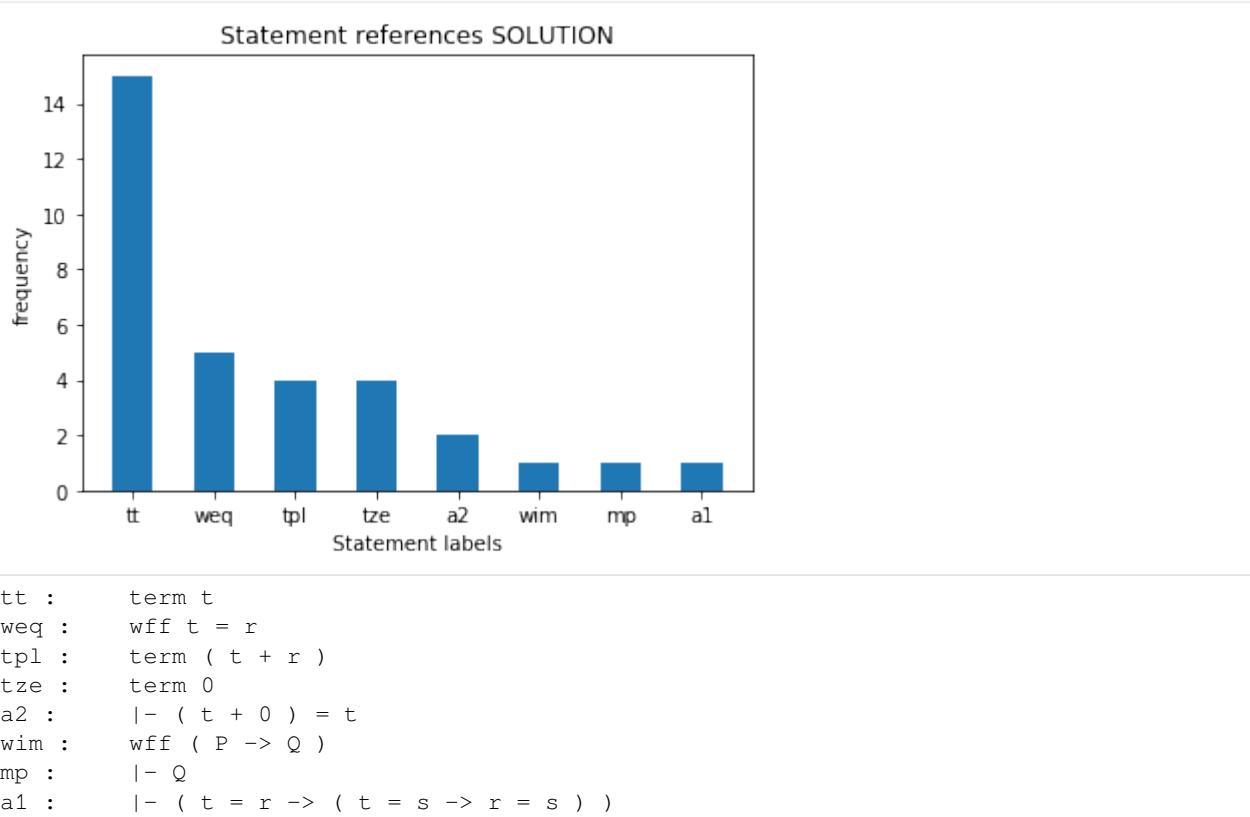

plt.bar(xs, ys_in, 0.5, align='center')

plt.title("Statement references SOLUTION")
plt.xticks(xs, [c[0] for c in coords])

plt.xlabel('Statement labels')
plt.ylabel('frequency')

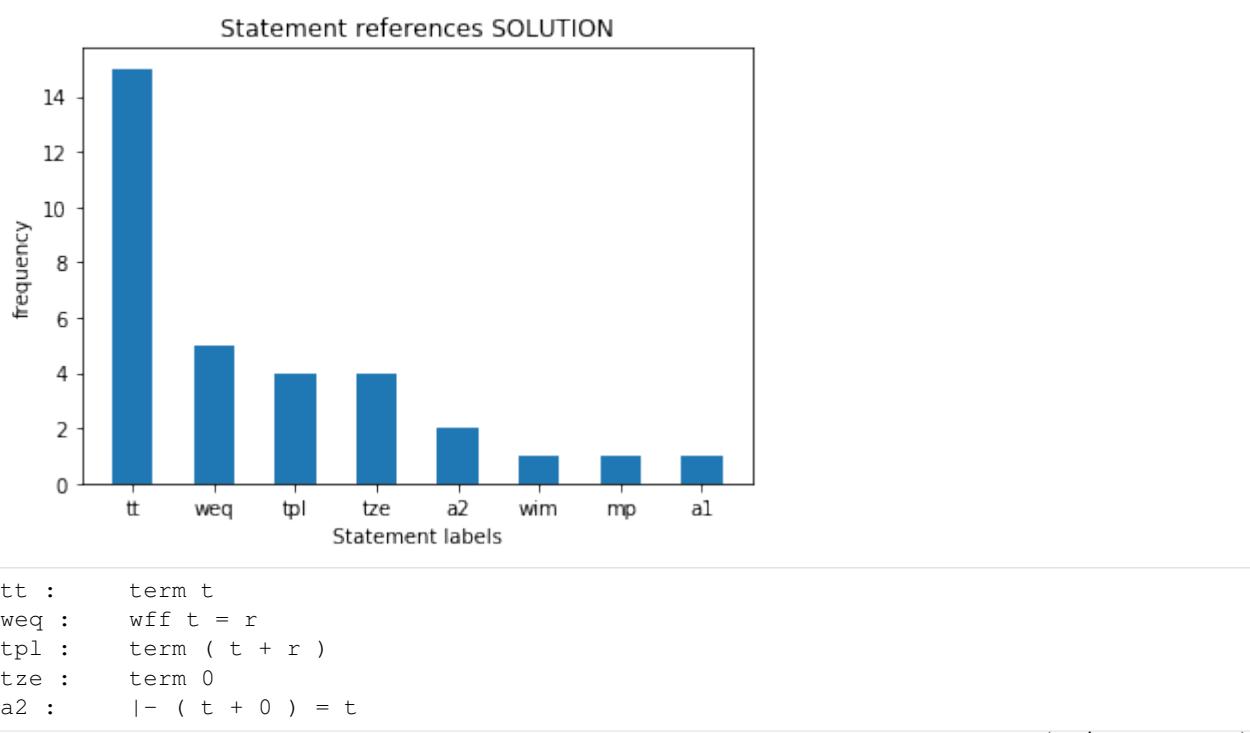

plt.show()

for c in coords:
    print(c[0], ':', '\t', db_mm[c[0]]['sequence'])
```

</div>

[10] :

(continued from previous page)

```
wim :      wff ( P -> Q )
mp :      |- Q
a1 :      |- ( t = r -> ( t = s -> r = s ) )
```

Part B

B1 Theory

Write the solution in separate ``theory.txt`` file

B1.1 my_fun

Given a list L of n elements, please compute the asymptotic computational complexity of the following function, explaining your reasoning.

```
def my_fun(L):
    n = len(L)
    if n <= 1:
        return 1
    else:
        L1 = L[0:n//2]
        L2 = L[n//2:]
        a = my_fun(L1) + max(L1)
        b = my_fun(L2) + max(L2)
        return a + b
```

B1.2 differences

Briefly describe the main differences between the stack and queue data structures. Please provide an example of where you would use one or the other.

B2 plus_one

Open a text editor and edit file digi_lists.py

You are given this class:

```
class DigiList:
    """
        This is a stripped down version of the LinkedList as previously seen,
        which can only hold integer digits 0-9
        NOTE: there is also a _last pointer
    """
```

Implement this method:

```
def plus_one(self):
    """ MODIFIES the digi list by summing one to the integer number it represents
        - you are allowed to perform multiple scans of the linked list
        - remember the list has a _last pointer

        - MUST execute in O(N) where N is the size of the list
        - DO *NOT* create new nodes EXCEPT for special cases:
            a. empty list ( [] -> [5] )
            b. all nines ( [9,9,9] -> [1,0,0,0] )
        - DO *NOT* convert the digi list to a python int
        - DO *NOT* convert the digi list to a python list
        - DO *NOT* reverse the digi list
    """

```

Test: python3 -m unittest digi_list_test.PlusOneTest

Example:

```
[11]: from digi_list_sol import *

dl = DigiList()

dl.add(9)
dl.add(9)
dl.add(7)
dl.add(3)
dl.add(9)
dl.add(2)

print(dl)
```

DigiList: 2,9,3,7,9,9

```
[12]: dl.last()
```

```
[12]: 9
```

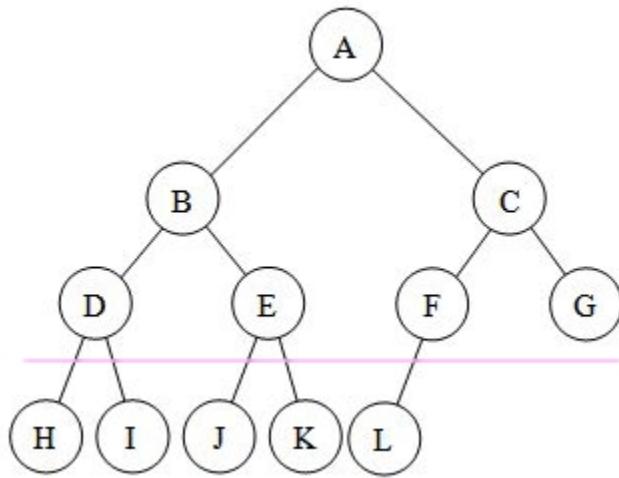

```
[13]: dl.plus_one()
```

```
[14]: print(dl)
```

DigiList: 2,9,3,8,0,0

B3 add_row

Open a text editor and edit file bin_tree.py.

Now implement this method:

```
def add_row(self, elems):
    """ Takes as input a list of data and MODIFIES the tree by adding
    a row of new leaves, each having as data one element of elems,
    in order.

    - elems size can be less than 2*/leaves/
    - if elems size is more than 2*/leaves/, raises ValueError
    - for simplicity, you can assume self is a perfect
      binary tree, that is a binary tree in which all interior nodes
      have two children and all leaves have the same depth
    - MUST execute in O(n+/elems/) where n is the size of the tree
    - DO *NOT* use recursion
    - implement it with a while and a stack (as a Python list)
    """

```

Test: python3 -m unittest bin_tree_test.AddRowTest

Example:

```
[15]: from bin_tree_sol import *
from bin_tree_test import bt

t = bt('a',
       bt('b',
           bt('d'),
           bt('e')),
       bt('c',
           bt('f'),
           bt('g')))

print(t)
```

```
a
| b
| | d
```

(continues on next page)

(continued from previous page)

```
| ↘e
└c
  ↘f
    ↘g
```

```
[16]: t.add_row(['h', 'i', 'j', 'k', 'l'])
```

```
[17]: print(t)
```

```
a
├── b
│   ├── d
│   │   ├── h
│   │   └── i
│   └── e
│       ├── j
│       └── k
└── c
    ├── f
    ├── l
    └── g
```

2.1.13 Exam - Mon 10, Feb 2020

Scientific Programming - Data Science @ University of Trento

[Download exercises and solution](#)

Introduction

- Taking part to this exam erases any vote you had before

What to do

- 1) Download `sciprog-ds-2020-02-10-exam.zip` and extract it on your desktop. Folder content should be like this:

```
sciprog-ds-2020-02-10-FIRSTNAME-LASTNAME-ID
  exam-2020-02-10.ipynb
  B1-theory.txt
  B2_italian_queue_v2.py
  B2_italian_queue_v2_test.py
  jupman.py
  sciprog.py
```

- 2) Rename `sciprog-ds-2020-02-10-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2020-02-10-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins. If it takes longer, leave it and try another exercise.

4) When done:

- if you have unitn login: zip and send to examina.icts.unitn.it/studente¹⁰³
- If you don't have unitn login: tell instructors and we will download your work manually

Part A

Open Jupyter and start editing this notebook `exam-2020-02-10.ipynb`

WordNet¹⁰⁴® is a large lexical database of English. Nouns, verbs, adjectives and adverbs are grouped into sets of cognitive synonyms (synsets), each expressing a distinct concept. Synsets are interlinked by means of semantic relations. The resulting network of related words and concepts can be navigated with the browser. WordNet is also freely and publicly available for download, making it a useful tool for computational linguistics and natural language processing. Princeton University "About WordNet." [WordNet](#)¹⁰⁵. Princeton University. 2010

In Python there are specialized libraries to read WordNet like [NLTK](#)¹⁰⁶, but for the sake of this exercise, you will parse the noun database as a text file which can be read line by line.

We will focus on *names* and how they are linked by *IS A* relation, for example, a dalmatian *IS A* dog (*IS A* is also called *hypernym* relation)

A1 parse_db

First, you will begin with parsing an excerpt of wordnet data/dogs.noun, which is a noun database shown here in its entirety.

According to documentation¹⁰⁷, a noun database begins with several lines containing a copyright notice, version number, and license agreement: these lines all begin with **two spaces** and the line number like

```
1 This software and database is being provided to you, the LICENSEE, by
2 Princeton University under the following license. By obtaining, using
3 and/or copying this software and database, you agree that you have
```

Afterwards, each of following lines describe a noun synset, that is, a unique concept identified by a number called `synset_offset`.

- each synset can have many words to represent it - for example, the noun synset 02112993 has 03 (`w_cnt`) words `dalmatian`, `coach_dog`, `carriage_dog`.
- a synset can be linked to other ones by relations. The dalmatian synset is linked to 002 (`p_cnt`) other synsets: to synset 02086723 by the @ relation, and to synset 02113184 by the ~ relation. For our purposes, you can focus on the @ symbol which means *IS A* relation (also called *hypernym*). If you search for a line starting with 02086723, you will see it is the synset for `dog`, so Wordnet is telling us a dalmatian *IS A* dog.

WARNING 1: lines can be quite long so if they appear to span multiple lines don't be fooled : remember each name definition only occupies one single line with no carriage returns!

¹⁰³ <http://examina.icts.unitn.it/studente>

02116752 05 n 01 wolf 0 007 @ 02085998 n 0000 #m 02086515 n 0000 ~ 01324999 n 0000 ~ 02117019 n 0000 ~ 02117200 n 0000 ~ 02117364 n 0000 ~ 02117507 n 0000 | any of various predatory carnivorous canine mammals of North America and Eurasia that usually hunt in packs

Field description

While parsing, skip the copyright notice. Then, each name definition follows the following format:

```
synset_offset lex_filenum ss_type w_cnt word lex_id [word lex_id...] p_cnt [ptr...] ↴  
| gloss
```

- **synset_offset**: Number identifying the synset, for example 02112993. **MUST be converted to a Python int**
- **lex_filenum**: Two digit decimal integer corresponding to the lexicographer file name containing the synset, for example 03. **MUST be converted to a Python int**
- **ss_type**: One character code indicating the synset type, store it as a string.
- **w_cnt**: Two digit **hexadecimal** integer indicating the number of words in the synset, for example b3. **MUST be converted to a Python int**.

WARNING: w_cnt is expressed as **hexadecimal**!

To convert an hexadecimal number like b3 to a decimal int you will need to specify the base 16 like in `int('b3', 16)` which produces the decimal integer 179.

- Afterwards, there will be **w_cnt** words, each represented by two fields (for example, `dalmatian 0`). You **MUST** store these fields into a Python list called `words` containing a dictionary for each word, having these fields:
 - **word**: ASCII form of a word (example: `dalmatian`), with spaces replaced by underscore characters (`_`)
 - **lex_id**: One digit **hexadecimal** integer (example: 0) that **MUST be converted to a Python int**

WARNING: lex_id is expressed as **hexadecimal**!

To convert an hexadecimal number like b3 to a decimal int you will need to specify the base 16 like in `int('b3', 16)` which produces the decimal integer 179.

- **p_cnt**: Three digit **decimal** integer indicating the number of pointers (that is, relations like for example *IS A*) from this synset to other synsets. **MUST be converted to a Python int**

WARNING: differently from w_cnt, the value p_cnt is expressed as **decimal**!

- Afterwards, there will be **p_cnt** pointers, each represented by four fields `pointer_symbol` `synset_offset` `pos` `source/target` (for example, `@ 02086723 n 0000`). **You MUST store these fields into a Python list called** `ptrs` containing a dictionary for each pointer, having these fields:

- pointer_symbol: a symbol indicating the type of relation, for example @ (which represents *IS A* relation)
- synset_offset : the identifier of the target synset, for example 02086723. **You MUST convert this to a Python int**
- pos: just parse it as a string (we will not use it)
- source/target: just parse it as a string (we will not use it)

WARNING: DO NOT assume first pointer is an @ (*IS A*) !!

In the full database, the root synset *entity* can't possibly have a parent synset:

```
0      1  2 3  4      5 6   7 8      9 10   11 12      13 14   15 16      17 18
00001740 03 n 01 entity 0 003 ~ 00001930 n 0000 ~ 00002137 n 0000 ~ 04431553 n ↴
↳0000 | that which is perceived or known or inferred to have its own distinct
↳existence (living or nonliving)
```

- gloss: Each synset contains a gloss (that is, a description). A gloss is represented as a vertical bar (|), followed by a text string that continues until the end of the line. For example, a large breed having a smooth white coat with black or brown spots; originated in Dalmatia

implement parse_db

```

A2 to_adj

Implement a function `to_adj` which takes the parsed db and RETURN a graph-like data structure in adjacency list format. Each node represent a synset - as label use the first word of the synset. A node is linked to another one if there is a *IS A* relation among the nodes, so use the @ symbol to filter the hypernyms.

IMPORTANT: not all linked synsets are present in the dogs excerpt.

HINT: If you couldn't implement the `parse_db` function properly, use as data the result of the previous print.

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

data-jupman-show="Show solution"

data-jupman-hide="Hide">Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[4]: def to_adj(db):
    ret = {}

    for d in db.values():
        targets = []
        for ptr in d['ptrs']:
            if ptr['pointer_symbol'] == '@':
                if ptr['synset_offset'] in db:
                    targets.append(db[ptr['synset_offset']]['words'][0]['word'])
                else:
                    # targets.append(ptr['synset_offset'])
            ret[d['words'][0]['word']] = targets
    return ret

dogs_graph = to_adj(dogs_db)

 'working_dog': ['dog']}
```

Check results

If parsing is right, you should get the following graph

DO NOT implement any drawing function, this is just for checking your results

```
[5]: from sciprog import draw_adj
draw_adj(dogs_graph, options={'graph': {'rankdir': 'BT'}})
```

A.3 hist

You are given a dictionary mapping each relation symbol (i.e. @) to its description (i.e. Hypernym).

Implement a function to draw the histogram of relation frequencies found in the relation links of the entire Wordnet, which can be loaded from the file `data/data.noun`. If you previously implemented `parse_db` in a correct way, you should be able to load the whole db. If for any reasons you can't, try at least to draw the histogram of frequencies found in `dogs_db`

- sort the histogram from greatest to lowest frequency
- do not count the relations containing the word 'domain' inside (upper/lowercase)
- do not count the "@" relation
- display the relation names nicely, adding newlines if necessary

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

```

```

Part B

B1 Theory

Write the solution in separate ``theory.txt`` file

B1.1 complexity

Given a list L of n elements, please compute the asymptotic computational complexity of the following function, explaining your reasoning. Any ideas on how to improve the complexity of this code?

```
def my_fun(L):
    n = len(L)
    out = []
    for i in range(n-2):
        out.insert(0, L[i] + L[i+1] + L[i+2])
    return out
```

B1.2 graph visits

Briefly describe the two classic ways of visiting the nodes of a graph.

B2 ItalianQueue v2

Open a text editor and have a look at file `italian_queue_v2.py`

In the original v1 implementation of the ItalianQueue we've already seen in class¹⁰⁸, `enqueue` can take $O(n)$: you will improve it by adding further indexing so it runs in $O(1)$

An ItalianQueue is modelled as a LinkedList with two pointers, `a_head` and `a_tail`:

- an element is enqueued scanning from `_head` until a matching group is found, in which case the element is inserted after (that is, at the right) of the matching group, otherwise the element is appended at the very end marked by `_tail`

¹⁰⁸ <https://sciprog.davidleoni.it/queues/queues.html#3.-ItalianQueue>

- an element is dequeued from the `_head`

For this improved v2 version, you will use an additional dictionary `_tails` which associates to each group present in the queue the node at the tail of that group sequence. This way, instead of scanning you will be able to directly jump to insertion point.

```
class ItalianQueue:

    def __init__(self):
        """ Initializes the queue.

            - Complexity: O(1)
        """
        self._head = None
        self._tail = None
        self._tails = {}      # ----- NEW !
        self._size = 0
```

Example:

If we have the following situation:

```

data  : a -> b -> c -> d -> e -> f -> g -> h
group : x     x     y     y     y     z     z     z
        ^     ^           ^           ^
        |     |           |           |
        | _tails[x]      _tails[y]      _tails[z]
        |
        _head                      _tail

```

By calling

```
q.enqueue('i', 'y')
```

We get:

```

data  : a -> b -> c -> d -> e -> i -> f -> g -> h
group : x     x     y     y     y     y     z     z     z
        ^     ^
        |     |
        | _tails[x]           _tails[y]           _tails[z]
        |
        _head                  _tail

```

We can see here the complete run:

```
[8]: from italian_queue_v2_sol import *
q = ItalianQueue()
print(q)

ItalianQueue:

    _head: None
    _tail: None
    _tails: {}
```

```
[10]: print(q)
ItalianQueue: a
    x
    _head: Node(a,x)
    _tail: Node(a,x)
    _tails: {'x': Node(a,x),}
```

```
[11]: q.enqueue('c','y')      # 'c' belongs to new group 'y', goes to the end of the queue
```

```
[12]: print(q)
ItalianQueue: a->c
    x  y
    _head: Node(a,x)
    _tail: Node(c,y)
    _tails: {'y': Node(c,y),
              'x': Node(a,x),}
```

```
[13]: q.enqueue('d','y')      # 'd' belongs to existing group 'y', goes to the end of the
      ↪group
```

```
[14]: print(q)
ItalianQueue: a->c->d
    x  y  y
    _head: Node(a,x)
    _tail: Node(d,y)
    _tails: {'y': Node(d,y),
              'x': Node(a,x),}
```

```
[15]: q.enqueue('b','x')      # 'b' belongs to existing group 'x', goes to the end of the
      ↪group
```

```
[16]: print(q)
ItalianQueue: a->b->c->d
    x  x  y  y
    _head: Node(a,x)
    _tail: Node(d,y)
    _tails: {'y': Node(d,y),
              'x': Node(b,x),}
```

```
[17]: q.enqueue('f','z')      # 'f' belongs to new group, goes at the end of the queue
```

```
[18]: print(q)
ItalianQueue: a->b->c->d->f
    x  x  y  y  z
    _head: Node(a,x)
    _tail: Node(f,z)
    _tails: {'z': Node(f,z),
              'y': Node(d,y),
              'x': Node(b,x),}
```

```
[19]: q.enqueue('e', 'y')    # 'e' belongs to an existing group 'y', goes at the end of the
      ↪group
```

```
[20]: print(q)

ItalianQueue: a->b->c->d->e->f
              x  x  y  y  y  z
              _head: Node(a,x)
              _tail: Node(f,z)
              _tails: {'z': Node(f,z),
                        'y': Node(e,y),
                        'x': Node(b,x),}
```

```
[21]: q.enqueue('g', 'z')    # 'g' belongs to an existing group 'z', goes at the end of the
      ↪group
```

```
[22]: print(q)

ItalianQueue: a->b->c->d->e->f->g
              x  x  y  y  y  z  z
              _head: Node(a,x)
              _tail: Node(g,z)
              _tails: {'z': Node(g,z),
                        'y': Node(e,y),
                        'x': Node(b,x),}
```

```
[23]: q.enqueue('h', 'z')    # 'h' belongs to an existing group 'z', goes at the end of the
      ↪group
```

```
[24]: print(q)

ItalianQueue: a->b->c->d->e->f->g->h
              x  x  y  y  y  z  z  z
              _head: Node(a,x)
              _tail: Node(h,z)
              _tails: {'z': Node(h,z),
                        'y': Node(e,y),
                        'x': Node(b,x),}
```

```
[25]: q.enqueue('h', 'z')    # 'h' belongs to an existing group 'z', goes at the end of the
      ↪group
```

```
[26]: print(q)

ItalianQueue: a->b->c->d->e->f->g->h->h
              x  x  y  y  y  z  z  z
              _head: Node(a,x)
              _tail: Node(h,z)
              _tails: {'z': Node(h,z),
                        'y': Node(e,y),
                        'x': Node(b,x),}
```

```
[27]: q.enqueue('i', 'y')    # 'i' belongs to an existing group 'y', goes at the end of the
      ↪group
```

```
[28]: print(q)

ItalianQueue: a->b->c->d->e->i->f->g->h->h
              x   x   y   y   y   y   z   z   z   z
              _head: Node(a,x)
              _tail: Node(h,z)
              _tails: {'z': Node(h,z),
                        'y': Node(i,y),
                        'x': Node(b,x),}
```

Dequeue is always from the head, without taking in consideration the group:

```
[29]: q.dequeue()
```

```
[29]: 'a'
```

```
[30]: print(q)
```

```
ItalianQueue: b->c->d->e->i->f->g->h->h
              x   y   y   y   y   z   z   z   z
              _head: Node(b,x)
              _tail: Node(h,z)
              _tails: {'z': Node(h,z),
                        'y': Node(i,y),
                        'x': Node(b,x),}
```

```
[31]: q.dequeue()      # removed last member of group 'x', key 'x' disappears from _tails['x']
```

```
[31]: 'b'
```

```
[32]: print(q)
```

```
ItalianQueue: c->d->e->i->f->g->h->h
              y   y   y   y   z   z   z   z
              _head: Node(c,y)
              _tail: Node(h,z)
              _tails: {'z': Node(h,z),
                        'y': Node(i,y),}
```

```
[33]: q.dequeue()
```

```
[33]: 'c'
```

```
[34]: print(q)
```

```
ItalianQueue: d->e->i->f->g->h->h
              y   y   y   z   z   z   z
              _head: Node(d,y)
              _tail: Node(h,z)
              _tails: {'z': Node(h,z),
                        'y': Node(i,y),}
```

B2.1 enqueue

Implement enqueue:

```
def enqueue(self, v, g):
    """ Enqueues provided element v having group g, with the following
    criteria:

        Queue is scanned from head to find if there is another element
        with a matching group:
            - if there is, v is inserted after the last element in the
              same group sequence (so to the right of the group)
            - otherwise v is inserted at the end of the queue

        - MUST run in O(1)
    """

```

Testing: python3 -m unittest italian_queue_test.EnqueueTest

B2.2 dequeue

Implement dequeue:

```
def dequeue(self):
    """ Removes head element and returns it.

        - If the queue is empty, raises a LookupError.
        - MUST perform in O(1)
        - REMEMBER to clean unused _tails keys
    """

```

IMPORTANT: you can test ``dequeue`` even if you didn't implement ``enqueue`` correctly

Testing: python3 -m unittest italian_queue_test.DequeueTest

[]:

2.1.14 Exam - Tue 16, Jun 2020

Scientific Programming - Data Science @ University of Trento

Download exercises and solutions

Introduction

- Taking part to this exam erases any vote you had before

What to do

- 1) Download `sciprog-ds-2020-06-16-exam.zip` and extract it on your desktop. Folder content should be like this:

```
sciprog-ds-2020-06-16-FIRSTNAME-LASTNAME-ID  
exam-2020-06-16.ipynb  
theory.txt  
linked_list.py  
linked_list_test.py  
bin_tree.py  
bin_tree_test.py
```

- 2) Rename `sciprog-ds-2020-06-16-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2020-06-16-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins.
If it takes longer, leave it and try another exercise.
- 4) When done:
 - if you have unitn login: zip and send to examina.icts.unitn.it/studente¹⁰⁹
 - If you don't have unitn login: tell instructors and we will download your work manually

Part A - Zoom surveillance

A training center holds online courses with [Zoom software](#)¹¹⁰. Participants attendance is mandatory, and teachers want to determine who left, when and for what reason. Zoom allows to save a meeting log in a sort of CSV format which holds the timings of joins and leaves of each student. You will clean the file content and show relevant data in charts.

Basically, you are going to build a surveillance system to monitor YOU. Welcome to digital age.

CSV format

You are provided with the file `UserQos_12345678901.csv`. Unfortunately, it is a weird CSV which actually looks like two completely different CSVs were merged together, one after the other. It contains the following:

- 1st line: general meeting header
- 2nd line: general meeting data
- 3rd line: empty
- 4th line completely different header for participant sessions for that meeting. Each session contains a join time and a leave time, and each participant can have multiple sessions in a meeting.
- 5th line and following: sessions data

The file has lots of useless fields, try to explore it and understand the format (if you want, you may use LibreOffice Calc to help yourself)

Here we only show the few fields we are actually interested in, and examples of transformations you should apply:

From general meeting information section:

¹⁰⁹ <http://examina.icts.unitn.it/studente>

¹¹⁰ <https://zoom.us/>

- Meeting ID: 123 4567 8901
- Topic: Hydraulics Exam
- Start Time: "Apr 17, 2020 02:00 PM" should become Apr 17, 2020

From participant sessions section:

- Participant: Luigi
- Join Time: 01:54 PM should become 13:54
- Leave Time: 03:10 PM (Luigi got disconnected from the meeting. Reason: Network connection error.) should be split into two fields, one for actual leave time in 15:10 format and another one for disconnection reason.

There are 3 possible disconnection reasons (try to come up with a general way to parse them - notice that there is no dot at the end of transformed string):

- (Luigi got disconnected from the meeting. Reason: Network connection error.) should become Network connection error
- (Bowser left the meeting. Reason: Host closed the meeting.) should become Host closed the meeting
- (Princess Toadstool left the meeting. Reason: left the meeting.) should become left the meeting

Your first goal will be to load the dataset and restructure the data so it looks like this:

```
[[{"meeting_id": "123 4567 8901", "topic": "Hydraulics Exam", "date": "Apr 17, 2020", "participant": "Luigi", "join_time": "13:54", "leave_time": "15:10", "reason": "Network connection error"}, {"meeting_id": "123 4567 8901", "topic": "Hydraulics Exam", "date": "Apr 17, 2020", "participant": "Luigi", "join_time": "15:12", "leave_time": "15:54", "reason": "left the meeting"}, {"meeting_id": "123 4567 8901", "topic": "Hydraulics Exam", "date": "Apr 17, 2020", "participant": "Mario", "join_time": "14:02", "leave_time": "14:16", "reason": "Network connection error"}, {"meeting_id": "123 4567 8901", "topic": "Hydraulics Exam", "date": "Apr 17, 2020", "participant": "Mario", "join_time": "14:19", "leave_time": "15:02", "reason": "Network connection error"}, {"meeting_id": "123 4567 8901", "topic": "Hydraulics Exam", "date": "Apr 17, 2020", "participant": "Mario", "join_time": "15:04", "leave_time": "15:50", "reason": "Network connection error"}, {"meeting_id": "123 4567 8901", "topic": "Hydraulics Exam", "date": "Apr 17, 2020", "participant": "Mario", "join_time": "15:52", "leave_time": "15:55", "reason": "Network connection error"}, {"meeting_id": "123 4567 8901", "topic": "Hydraulics Exam", "date": "Apr 17, 2020", "participant": "Mario", "join_time": "15:56", "leave_time": "16:00", "reason": "Host closed the meeting"}, {"...}]]
```

To fix the times, you will first need to implement the following function.

Open Jupyter and start editing this notebook exam-2020-06-16.ipynb

A1 time24

```
[1]: def time24(t):
    """ Takes a time string like '06:27 PM' and outputs a string like 18:27
    """
    #jupman_raise
    if t.endswith('AM'):
        if t.startswith('12:00'):
            return '00:00'
        else:
            return t.replace(' AM', '')
    else:
        if t.startswith('12:00'):
            return '12:00'

    h = '%0.d' % (int(t.split(':')[0]) + 12)

    return h + ':' + t.split(':')[1].replace(' PM', '')
#/jupman_raise

assert time24('12:00 AM') == '00:00' # midnight
assert time24('01:06 AM') == '01:06'
assert time24('09:45 AM') == '09:45'
assert time24('12:00 PM') == '12:00' # special case, it's actually midday
assert time24('01:27 PM') == '13:27'
assert time24('06:27 PM') == '18:27'
assert time24('10:03 PM') == '22:03'
```

A2 load

Implement a function which loads the file `UserQos_12345678901.csv` and RETURN a list of lists.

To parse the file, you can use simple [CSV parsing¹¹¹](#) as seen in class (there is no need to use pandas)

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[2]: import csv

def load(filepath):

    ret = []
    with open(filepath, encoding='utf-8', newline='') as f:

        lettore = csv.reader(f, delimiter=',')
        next(lettore)
        riga_meeting = next(lettore)
        meeting_id = riga_meeting[0]
        topic = riga_meeting[1]
        meeting_date = riga_meeting[7]
        next(lettore) # riga vuota
        next(lettore) # secondo header
        ret.append(['meeting_id', 'topic', 'date', 'participant', 'join_time', 'leave_time', 'reason'])
```

(continues on next page)

¹¹¹ <https://sciprog.davidleoni.it/formats/format-sol.html#2.-File-CSV>

(continued from previous page)

```

for riga in lettore:
    session = {}
    if len(riga) > 0:
        ret.append([meeting_id,
                    topic,
                    meeting_date[:12],
                    riga[0],
                    time24(riga[10]),
                    time24(riga[11].split('(')[0]),
                    riga[11].split('Reason: ')[1].split('.')[0]))
return ret

meeting_log = load('UserQos_12345678901.csv')

from pprint import pprint
pprint(meeting_log, width=150)

assert meeting_log == EXPECTED_MEETING_LOG # all table

```

A3.1 duration

Given two times as strings a and b in format like 17:34, RETURN the duration in minutes between them as an integer.

To calculate gap durations, we assume a meeting NEVER ends after midnight

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[4]: def duration(a, b):

    asp = a.split(':')
    ta = int(asp[0])*60+int(asp[1])
    bsp = b.split(':')
    tb = int(bsp[0])*60 + int(bsp[1])
    return tb - ta

assert duration('15:00', '15:34') == 34
assert duration('15:00', '17:34') == 120 + 34
assert duration('15:50', '16:12') == 22
assert duration('09:55', '11:06') == 5 + 60 + 6
assert duration('00:00', '00:01') == 1
#assert duration('11:58', '00:01') == 3 # no need to support this case !!
```

```
</div>

[4]: def duration(a, b):
    raise Exception('TODO IMPLEMENT ME !')

assert duration('15:00', '15:34') == 34
assert duration('15:00', '17:34') == 120 + 34
assert duration('15:50', '16:12') == 22
assert duration('09:55', '11:06') == 5 + 60 + 6
assert duration('00:00', '00:01') == 1
#assert duration('11:58', '00:01') == 3 # no need to support this case !!
```

A3.2 calc_stats

We want to know something about the time each participant has been disconnected from the exam. We call such intervals gaps, which are the difference between a session leave time and **successive** session join time.

Implement the function `calc_stats` that given a cleaned log produced by `load`, RETURN a dictionary mapping each participant to a dictionary with these statistics:

- `max_gap` : the longest time in minutes in which the participant has been disconnected
- `gaps` : the number of disconnections happened to the participant during the meeting
- `time_away` : the total time in minutes during which the participant has been disconnected during the meeting

To calculate gap durations, **we assume a meeting NEVER ends after midnight**

For the data format details, see `EXPECTED_STATS` below.

To test the function, you DON'T NEED to have correctly implemented previous functions

```
<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"
  data-jupman-show="Show solution"
  data-jupman-hide="Hide">Show solution</a><div class="jupman-sol jupman-sol-code" style="display:none">
```

```
[5]: def calc_stats(log):

    ret = {}

    last_sessions = {}

    first = True
    for session in log:
        if first:
            first = False
            continue
        date = session[2]
        participant = session[3]
        join_time = session[4]
        leave_time = session[5]
        reason = session[6]

        if participant not in ret:
            ret[participant] = {'max_gap': 0,
                               'gaps': 0,
```

(continues on next page)

(continued from previous page)

```

        'time_away':0
    }

    if participant in last_sessions:
        last_leave_time = last_sessions[participant][5]
        gap = duration(last_leave_time, join_time)
        ret[participant]['max_gap'] = max(gap, ret[participant]['max_gap'])
        ret[participant]['gaps'] += 1
        ret[participant]['time_away'] += gap

    last_sessions[participant] = session
return ret

```

```

stats = calc_stats(meeting_log)

# in case you had trouble implementing load function, use this:
#stats = calc_stats(EXPECTED_MEETING_LOG)

```

```
stats
```

```
[5]: {'Bowser': {'gaps': 3, 'max_gap': 24, 'time_away': 38},
      'Luigi': {'gaps': 1, 'max_gap': 2, 'time_away': 2},
      'Mario': {'gaps': 4, 'max_gap': 3, 'time_away': 8},
      'Princess Toadstool': {'gaps': 0, 'max_gap': 0, 'time_away': 0},

        'Luigi': {'gaps': 1, 'max_gap': 2, 'time_away': 2},
        'Mario': {'gaps': 4, 'max_gap': 3, 'time_away': 8},
        'Princess Toadstool': {'gaps': 0, 'max_gap': 0, 'time_away': 0},
        'Wario': {'gaps': 4, 'max_gap': 15, 'time_away': 25}}
```

```
assert stats == EXPECTED_STATS
```

A4 viz

Produce a bar chart of the statistics you calculated before. For how to do it, see examples in [Visualiation tutorial](#)¹¹²

- participant names MUST be sorted in alphabetical order
- remember to put title, legend and axis labels

To test the function, you DON'T NEED to have correctly implemented previous functions

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[7]: %matplotlib inline

import numpy as np
import matplotlib.pyplot as plt

def viz(stats):

    xs = np.arange(len(stats))
    ys_max_gap = []
    ys_time_away = []

    labels = list(sorted(stats.keys()))

    for participant in sorted(stats):
        pstats = stats[participant]
        ys_max_gap.append(pstats['max_gap'])
        ys_time_away.append(pstats['time_away'])

    width = 0.35
    fig, ax = plt.subplots(figsize=(10,3))
    rects1 = ax.bar(xs - width/2, ys_max_gap, width,
                    color='red', label='max gap')
    rects2 = ax.bar(xs + width/2, ys_time_away, width,
                    color='darkred', label='time_away')

    plt.xticks(xs, labels)

    ax.set_title('Disconnects SOLUTION')
    ax.legend()

    plt.ylabel('minutes')
    plt.savefig('surveillance.png')
    plt.show()

viz(stats)

def viz(stats):
    raise Exception('TODO IMPLEMENT ME !')

viz(stats)

# in case you had trouble implementing calc_stats, use this:
#viz(EXPECTED_STATS)
```

Part B

B1 Theory

Write the solution in separate theory.txt file

B1.1 complexity

Given a list L of n positive integers, please compute the asymptotic computational complexity of the following function, explaining your reasoning.

```
def my_max(L):
    M = -1
    for e in L:
        if e > M:
            M = e
    return M

def my_fun(L):
    n = len(L)
    out = 0
    for i in range(5):
        out = out + my_max(L[i:])
    return out
```

B1.2 describe

Briefly describe what a bidirectional linked list is. How does it differ from a queue?

B2 - LinkedList slice

Open a text editor and edit file `linked_list.py`

Implement the method `slice`:

```
def slice(self, start, end):
    """ RETURN a NEW LinkedList created by copying nodes of this list
        from index start INCLUDED to index end EXCLUDED

        - if start is greater or equal than end, returns an empty LinkedList
        - if start is greater than available nodes, returns an empty LinkedList
        - if end is greater than the available nodes, copies all items until the tail
        ↪without errors
        - if start index is negative, raises ValueError
        - if end index is negative, raises ValueError

        - IMPORTANT: All nodes in the returned LinkedList MUST be NEW
        - DO *NOT* modify original linked list
        - DO *NOT* add an extra size field
        - MUST execute in O(n), where n is the size of the list

    """

```

Testing: `python3 -m unittest linked_list_test.SliceTest`

Example:

```
[8]: from linked_list_sol import *
```

```
[9]: la = LinkedList()
la.add('g')
la.add('f')
la.add('e')
la.add('d')
la.add('c')
la.add('b')
la.add('a')
```

```
[10]: print(la)
LinkedList: a,b,c,d,e,f,g
```

Creates a **NEW** `LinkedList` copying nodes from index 2 INCLUDED up to index 5 EXCLUDED:

```
[11]: lb = la.slice(2,5)
```

```
[12]: print(lb)
LinkedList: c,d,e
```

Note original `LinkedList` is still intact:

```
[13]: print(la)
LinkedList: a,b,c,d,e,f,g
```

Special cases

If start is greater or equal than end, you get an empty LinkedList:

```
[14]: print(la.slice(5,3))
LinkedList:
```

If start is greater than available nodes, you get an empty LinkedList:

```
[15]: print(la.slice(10,15))
LinkedList:
```

If end is greater than the available nodes, you get a copy of all the nodes until the tail without errors:

```
[16]: print(la.slice(3,10))
LinkedList: d,e,f,g
```

Using negative indexes for either start ,end or both raises ValueError:

```
la.slice(-3,4)

-----
ValueError                                Traceback (most recent call last)
<ipython-input-184-e3380bb66e77> in <module>()
----> 1 la.slice(-3,4)

~/Da/prj/sciprog-ds/prj/exams/2020-06-16/linked_list_sol.py in slice(self, start, end)
    63
    64      if start < 0:
---> 65          raise ValueError('Negative values for start are not supported! %s'
  ↵' % start)
    66      if end < 0:
    67          raise ValueError('Negative values for end are not supported: %s'
  ↵% end)

ValueError: Negative values for start are not supported! -3
```

```
la.slice(1,-2)

-----
ValueError                                Traceback (most recent call last)
<ipython-input-185-8e09ec468c30> in <module>()
----> 1 la.slice(1,-2)

~/Da/prj/sciprog-ds/prj/exams/2020-06-16/linked_list_sol.py in slice(self, start, end)
    65          raise ValueError('Negative values for start are not supported! %s'
  ↵' % start)
    66      if end < 0:
---> 67          raise ValueError('Negative values for end are not supported: %s'
  ↵% end)
```

(continues on next page)

(continued from previous page)

```

68
69         ret = LinkedList()
ValueError: Negative values for end are not supported: -2

```

B3 BinaryTree prune_rec

Implement the method `prune_rec`:

```

def prune_rec(self, el):
    """ MODIFIES the tree by cutting all the subtrees that have their
        root node data equal to el. By 'cutting' we mean they are no longer linked
        by the tree on which prune is called.

        - if prune is called on a node having data equal to el, raises ValueError
        - MUST execute in O(n) where n is the number of nodes of the tree
        - NOTE: with big trees a recursive solution would surely
            exceed the call stack, but here we don't mind
    """

```

Testing: `python3 -m unittest bin_tree_test.PrunerRecTest`

Example:

```
[17]: from bin_tree_sol import *
from bin_tree_test import bt
```

```
[18]: t = bt('a',
           bt('b',
               bt('z'),
               bt('c',
                   bt('d'),
                   bt('z',
                       None,
                       bt('e'))),
               bt('z',
                   bt('f'),
                   bt('z',
                       None,
                       bt('g')))))
```

```
[19]: print(t)
```

```

a
| b
| | z
| | c
| | | d
| | | | z
| | | | |
| | | | | e
| | | | z
| | | | f
| | | | z

```

(continues on next page)

(continued from previous page)

```
    ↴  
↳g
```

```
[20]: t.prune_rec('z')
```

```
[21]: print(t)
```

```
a  
| b  
| | c

| |  
|  
|
```

```
[22]: t.prune_rec('c')
```

```
[23]: print(t)

Trying to prune the root will throw a ValueError:

2.1.15 Exam - Fri 17, Jul 2020

Scientific Programming - Data Science @ University of Trento

Download exercises and solutions

Introduction

- Taking part to this exam erases any vote you had before

What to do

- 1) Download `sciprog-ds-2020-07-17-exam.zip` and extract it on your desktop. Folder content should be like this:

```
sciprog-ds-2020-07-17-FIRSTNAME-LASTNAME-ID
exam-2020-07-17.ipynb
theory.txt
office_queue_exercise.py
office_queue_test.py
```

- 2) Rename `sciprog-ds-2020-07-17-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2020-07-17-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins. If it takes longer, leave it and try another exercise.
- 4) When done:
 - if you have unitn login: zip and send to examina.icts.unitn.it/studente¹¹³
 - If you don't have unitn login: tell instructors and we will download your work manually

Part A - NACE codes

https://ec.europa.eu/eurostat/ramon/nomenclatures/index.cfm?TargetUrl=LST_CLS_DLD&StrNom=NACE_REV2&StrLanguageCode=EN&StrLayoutCode=HIERARCHIC#

So you want to be a data scientist. Good, plenty of opportunities ahead!

After graduating, you might discover though that many companies require you to actually work as a freelancer: you will just need to declare to the state which type of economic activity you are going to perform, they say. Seems easy, but you will soon encounter a pretty bureaucratic problem: do public institutions even *know* what a data scientist is? If not, what is the closest category they recognize? Is there any specific *exclusion* that would bar you from entering that category?

If you are in Europe, you will be presented with a catalog of economic activities you can choose from called [NACE](#)¹¹⁴, which is then further specialized by various states (for example Italy's catalog is called [ATECO](#)¹¹⁵)

Sections

A NACE code is subdivided in a hierarchical, four-level structure. The categories at the highest level are called *sections*, here they are:

¹¹³ <http://examina.icts.unitn.it/studente>

¹¹⁴ https://ec.europa.eu/eurostat/ramon/nomenclatures/index.cfm?TargetUrl=LST_NOM_DTL&StrNom=NACE_REV2&StrLanguageCode=EN&IntPcKey=&StrLayoutCode=HIERARCHIC

¹¹⁵ <https://www.istat.it/it/archivio/17888>

Detail	
+ A	AGRICULTURE, FORESTRY AND FISHING Detail
+ B	MINING AND QUARRYING Detail
+ C	MANUFACTURING Detail
+ D	ELECTRICITY, GAS, STEAM AND AIR CONDITIONING SUPPLY Detail
+ E	WATER SUPPLY; SEWERAGE, WASTE MANAGEMENT AND REMEDIATION ACTIVITIES Detail
+ F	CONSTRUCTION Detail
+ G	WHOLESALE AND RETAIL TRADE; REPAIR OF MOTOR VEHICLES AND MOTORCYCLES Detail
+ H	TRANSPORTATION AND STORAGE Detail
+ I	ACCOMMODATION AND FOOD SERVICE ACTIVITIES Detail
+ J	INFORMATION AND COMMUNICATION Detail
+ K	FINANCIAL AND INSURANCE ACTIVITIES Detail
+ L	REAL ESTATE ACTIVITIES Detail
+ M	PROFESSIONAL, SCIENTIFIC AND TECHNICAL ACTIVITIES Detail
+ N	ADMINISTRATIVE AND SUPPORT SERVICE ACTIVITIES Detail
+ O	PUBLIC ADMINISTRATION AND DEFENCE; COMPULSORY SOCIAL SECURITY Detail
+ P	EDUCATION Detail
+ Q	HUMAN HEALTH AND SOCIAL WORK ACTIVITIES Detail
+ R	ARTS, ENTERTAINMENT AND RECREATION Detail
+ S	OTHER SERVICE ACTIVITIES Detail
+ T	ACTIVITIES OF HOUSEHOLDS AS EMPLOYERS; UNDIFFERENTIATED GOODS- AND SERVICES-PRODUCING ACTIVITIES OF HOUSEHOLDS FOR OWN USE Detail
+ U	ACTIVITIES OF EXTRATERRITORIAL ORGANISATIONS AND BODIES Detail

Section detail

If you drill down in say, section M, you will find something like this:

The first two digits of the code identify the *division*, the third digit identifies the *group*, and the fourth digit identifies the *class*:

M PROFESSIONAL, SCIENTIFIC AND TECHNICAL ACTIVITIES

69 Legal and accounting activities

69.1 Legal activities

69.10 Legal activities

69.2 Accounting, bookkeeping and auditing activities; tax consultancy

69.20 Accounting, bookkeeping and auditing activities; tax consultancy

70 Activities of head offices; management consultancy activities

70.1 Activities of head offices

70.10 Activities of head offices

70.2 Management consultancy activities

70.21 Public relations and communication activities

70.22 Business and other management consultancy activities

71 Architectural and engineering activities; technical testing and analysis

71.1 Architectural and engineering activities and related technical consultancy

71.11 Architectural activities

71.12 Engineering activities and related technical consultancy

71.2 Technical testing and analysis

71.20 Technical testing and analysis

72 Scientific research and development

72.1 Research and experimental development on natural sciences and engineering

72.11 Research and experimental development on biotechnology

72.19 Other research and experimental development on natural sciences and engineering

72.2 Research and experimental development on social sciences and humanities

72.20 Research and experimental development on social sciences and humanities

73 Advertising and market research

73.1 Advertising

73.11 Advertising agencies

73.12 Media representation

Let's pick for example *Advertising agencies*, which has code 73.11:

Level		Code	Spec	Description
1	Sec-tion	M	a single alphabetic char	PROFESSIONAL, SCIENTIFIC AND TECHNICAL ACTIVITIES
2	Divi-sion	73	two-digits	Advertising and market research
3	Group	73.1	three-digits, with dot after first two	Advertising
4	Class	73.12	four-digits, with dot after first two	Advertising agencies

Specifications

WARNING: CODES MAY CONTAIN ZEROES!

IF YOU LOAD THE CSV IN LIBREOFFICE CALC OR EXCEL, MAKE SURE IT IMPORTS EVERYTHING AS STRING!

WATCH OUT FOR CHOPPED ZEROES !

Zero examples:

- *Veterinary activities* contains a double zero *at the end* : 75.00
- group *Manufacture of beverages* contains a single zero at the end: 11.0
- *Manufacture of beer* contains zero *inside* : 11.05
- *Support services to forestry* contains a zero *at the beginning* : 02.4 which is different from 02.40 even if they have the same description !

The section level code is not integrated in the NACE code: For example, the activity *Manufacture of glues* is identified by the code 20.52, where 20 is the code for the division, 20.5 is the code for the group and 20.52 is the code of the class; section C, to which this class belongs, does not appear in the code itself.

There may be gaps (not very important for us): The divisions are coded consecutively. However, some “gaps” have been provided to allow the introduction of additional divisions without a complete change of the NACE coding.

NACE CSV

We provide you with a CSV **NACE_REV2_20200628_213139.csv** that contains all the codes. Try to explore it with LibreOffice Calc or pandas

Here we show some relevant parts (**NOTE:** for part A you will **NOT** need to use pandas)

```
[1]:  
import pandas as pd    # we import pandas and for ease we rename it to 'pd'  
import numpy as np     # we import numpy and for ease we rename it to 'np'  
  
pd.set_option('display.max_colwidth', -1)  
df = pd.read_csv('NACE_REV2_20200628_213139.csv', encoding='UTF-8')  
df.info()  
  
<class 'pandas.core.frame.DataFrame'>  
RangeIndex: 996 entries, 0 to 995  
Data columns (total 10 columns):  
Order            996 non-null int64  
Level            996 non-null int64  
Code             996 non-null object  
Parent           975 non-null object  
Description      996 non-null object  
This item includes 778 non-null object  
This item also includes 202 non-null object  
Rulings          134 non-null object  
This item excludes 507 non-null object  
Reference to ISIC Rev. 4 996 non-null object  
dtypes: int64(2), object(8)  
memory usage: 77.9+ KB
```

(continues on next page)

(continued from previous page)

We can focus on just these columns:

```
[3]: selection = [398482, 398488, 398530, 398608, 398482, 398518, 398521, 398567]

from IPython.display import display

example_df = df[['Order', 'Level', 'Code', 'Parent', 'Description', 'This item excludes']]
# Assuming the variable df contains the relevant DataFrame
example_df = example_df[example_df['Order'].isin(selection)]
display(example_df.style.set_properties(**{'white-space': 'pre-wrap',}))
```

A1 Extracting codes

Let's say European Commission wants to review the catalog to simplify it. One way to do it, could be to look for codes that have lots of exclusions, the reasoning being that trying to explain somebody something by stating what it is *not* often results in confusion.

A1.1 is_nace

Implement following function. NOTE: it was not explicitly required in the original exam but could help detecting words.

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

[4]:

```
def is_nace(word):
    """Given a word, RETURN True if the word is a NACE code, else otherwise"""

    # we could implement it also with regexes, here we use explicit methods:
    if len(word) == 1:
        return word.isalpha() and word.isupper()
    elif len(word) == 2:
        return word.isdigit()
    elif len(word) == 4:
        return word[:2].isdigit() and word[2] == '.' and word[3].isdigit()
    elif len(word) == 5:
        return word[:2].isdigit() and word[2] == '.' and word[3:4].isdigit()
    else:
        return False

assert is_nace('0') == False
assert is_nace('01') == True
assert is_nace('A') == True    # this is a Section
assert is_nace('AA') == False
assert is_nace('a') == False
assert is_nace('01.2') == True
assert is_nace('01.20') == True
assert is_nace('03.25') == True
assert is_nace('02.753') == False
assert is_nace('300') == False
assert is_nace('5012') == False
```

</div>

[4]:

```
def is_nace(word):
    """Given a word, RETURN True if the word is a NACE code, else otherwise"""
    raise Exception('TODO IMPLEMENT ME !')

assert is_nace('0') == False
assert is_nace('01') == True
assert is_nace('A') == True    # this is a Section
assert is_nace('AA') == False
assert is_nace('a') == False
assert is_nace('01.2') == True
assert is_nace('01.20') == True
assert is_nace('03.25') == True
```

(continues on next page)

(continued from previous page)

```
assert is_nace('02.753') == False
assert is_nace('300') == False
assert is_nace('5012') == False
```

A1.2 extract_codes

Implement following function which extracts codes from This item excludes column cells. For examples, see asserts.

Show solution<div class="jupman-sol" jupman-sol-code" style="display:none">

```
[5]: def extract_codes(text):
    """Extracts all the NACE codes from given text (a single string),
    and RETURN a list of the codes

    - also extracts section letters
    - list must have *no* duplicates
    """
    ret = []

    words = [word.strip(';,.:\()' for word in text.replace('-', ' ').split())
    for i in range(len(words)):

        if i < len(words) - 1 \
            and words[i].lower() == 'section' \
            and len(words[i+1]) == 1 \
            and words[i+1][0].isalpha():

            if words[i+1] not in ret:
                ret.append(words[i+1])
            else:
                if is_nace(words[i]) and words[i] not in ret:
                    ret.append(words[i])

    return ret

assert extract_codes('group 02.4') == ['02.4']
assert extract_codes('class 02.40') == ['02.40']
assert extract_codes('.') == []
assert extract_codes('exceeding 300 litres') == []
assert extract_codes('see 46.34') == ['46.34']
assert extract_codes('divisions 10 and 11') == ['10', '11']
assert extract_codes('(10.20)') == ['10.20']
assert extract_codes('(30.1, 33.15)') == ['30.1', '33.15']
assert extract_codes('as outlined in groups 85.1-85.4, i.e.') == ['85.1', '85.4']
assert extract_codes('see 25.99 see 25.99') == ['25.99'] # no duplicates
assert extract_codes('section A') == ['A']
assert extract_codes('in section G. Also') == ['G']
assert extract_codes('section F (Construction)') == ['F']
assert extract_codes('section A, section A') == ['A']
```

</div>

```
[5]: def extract_codes(text):
    """Extracts all the NACE codes from given text (a single string),
    and RETURN a list of the codes

    - also extracts section letters
    - list must have *no* duplicates
    """
    raise Exception('TODO IMPLEMENT ME !')

assert extract_codes('group 02.4') == ['02.4']
assert extract_codes('class 02.40') == ['02.40']
assert extract_codes('.') == []
assert extract_codes('exceeding 300 litres') == []
assert extract_codes('see 46.34') == ['46.34']
assert extract_codes('divisions 10 and 11') == ['10', '11']
assert extract_codes('(10.20)') == ['10.20']
assert extract_codes('(30.1, 33.15)') == ['30.1', '33.15']
assert extract_codes('as outlined in groups 85.1-85.4, i.e.') == ['85.1', '85.4']
assert extract_codes('see 25.99 see 25.99') == ['25.99'] # no duplicates
assert extract_codes('section A') == ['A']
assert extract_codes('in section G. Also') == ['G']
assert extract_codes('section F (Construction)') == ['F']
assert extract_codes('section A, section A') == ['A']
```

```
[6]: # MORE REALISTIC asserts:

t01 = """Agricultural activities exclude any subsequent processing of the agricultural products (classified under divisions 10 and 11 (Manufacture of food products and beverages) and division 12 (Manufacture of tobacco products)), beyond that needed to prepare them for the primary markets. The preparation of products for the primary markets is included here.

The division excludes field construction (e.g. agricultural land terracing, drainage, preparing rice paddies etc.) classified in section F (Construction) and ↴buyers and cooperative associations engaged in the marketing of farm products classified in section G. Also excluded is the landscape care and maintenance, which is classified in class 81.30.
"""
assert extract_codes(t01) == ['10', '11', '12', 'F', 'G', '81.30']

t01_15 = """This class excludes:
- manufacture of tobacco products, see 12.00
"""
assert extract_codes(t01_15) == ['12.00']

t03 = """This division does not include building and repairing of ships and boats (30.1, 33.15) and sport or recreational fishing activities (93.19). Processing of fish, crustaceans or molluscs is excluded, whether at land-based plants or on factory ships (10.20).
"""
assert extract_codes(t03) == ['30.1', '33.15', '93.19', '10.20']

t11_03 = """This class excludes:
- merely bottling and labelling, see 46.34 (if performed as part of wholesale) and 82.92 (if performed on a fee or contract basis)
"""

```

(continues on next page)

(continued from previous page)

```
"""
assert extract_codes(t11_03) == ['46.34', '82.92']

t01_64 = """This class excludes:
- growing of seeds, see groups 01.1 and 01.2
- processing of seeds to obtain oil, see 10.41
- research to develop or modify new forms of seeds, see 72.11
"""
assert extract_codes(t01_64) == ['01.1','01.2','10.41','72.11']

t02 = """Excluded is further processing of wood beginning with sawmilling and planing
of wood,
see division 16.
"""
assert extract_codes(t02) == ['16']

t09_90 = """This class excludes:
- operating mines or quarries on a contract or fee basis, see division 05, 07 or 08
- specialised repair of mining machinery, see 33.12
- geophysical surveying services, on a contract or fee basis, see 71.12
"""
assert extract_codes(t09_90) == ['05','07','08','33.12','71.12']
```

A2 build_db

Given a filepath pointing to a NACE CSV, reads the CSV and RETURN a dictionary mapping codes to dictionaries which hold the code descriptionn and a field with the list of excluded codes, for example:

```
{'01': {'description': 'Crop and animal production, hunting and related service',
    'activities': [
        'exclusions': ['10', '11', '12', 'F', 'G', '81.30']],
    '01.1': {'description': 'Growing of non-perennial crops', 'exclusions': []},
    '01.11': {'description': 'Growing of cereals (except rice), leguminous crops and oil
seeds',
        'exclusions': ['01.12', '01.13', '01.19', '01.26']},
    '01.12': {'description': 'Growing of rice', 'exclusions': []},
    '01.13': {'description': 'Growing of vegetables and melons, roots and tubers',
        'exclusions': ['01.28', '01.30']},
    ...
    ...
}
```

The complete desired output is in file expected_db.py

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[7]: def build_db(filepath):

    ret = {}
    import csv
    with open(filepath, encoding='utf-8', newline='') as f:
        my_reader = csv.DictReader(f, delimiter=',')
        for d in my_reader:
```

(continues on next page)

(continued from previous page)

```

diz = {'description' : d['Description'],
       'exclusions' : extract_codes(d['This item excludes'])}
ret[d['Code']] = diz
return ret

```

activities_db = build_db('NACE_REV2_20200628_213139.csv')
#activities_db

</div>

```
[7]: def build_db(filepath):
    raise Exception('TODO IMPLEMENT ME !')

activities_db = build_db('NACE_REV2_20200628_213139.csv')
#activities_db
```

A3 plot

Implement function `plot` which given a `db` as created at previous point and a code `level` among 1,2,3,4, plots the number of exclusions for all codes of that `exact` level (so do not include sublevels in the sum), sorted in reversed order.

- remember to plot title, notice it should shows the type of level (could be Section, Division, Group, or Class)
- try to display labels nicely as in the example output

(if you look at the graph, apparently European Union has a hard time defining what an artist is :-)

IMPORTANT: IF you couldn't implement the function `build_db`, you will still find the complete desired output in file `expected_db.py`, to import it write: `from expected_db import activities_db`

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[8]: %matplotlib inline
def plot(db, level):

    import matplotlib.pyplot as plt

    coords = [(code, len(db[code]['exclusions'])) for code in db if len(code.replace(
        '.', '')) == level]
    coords.sort(key=lambda c: c[1], reverse=True)

    coords = coords[:10]

    xs = [c[0] for c in coords]
    ys = [c[1] for c in coords]

    fig = plt.figure(figsize=(13, 6)) # width: 10 inches, height 3 inches

    plt.bar(xs, ys, 0.5, align='center')
```

(continues on next page)

(continued from previous page)

```

def fix_label(label):
    # coding horror, sorry
    return label.replace(' ', '\n').replace('\nand\n', ' and\n').replace('\nof\n', '\n'
    ↵of\n')

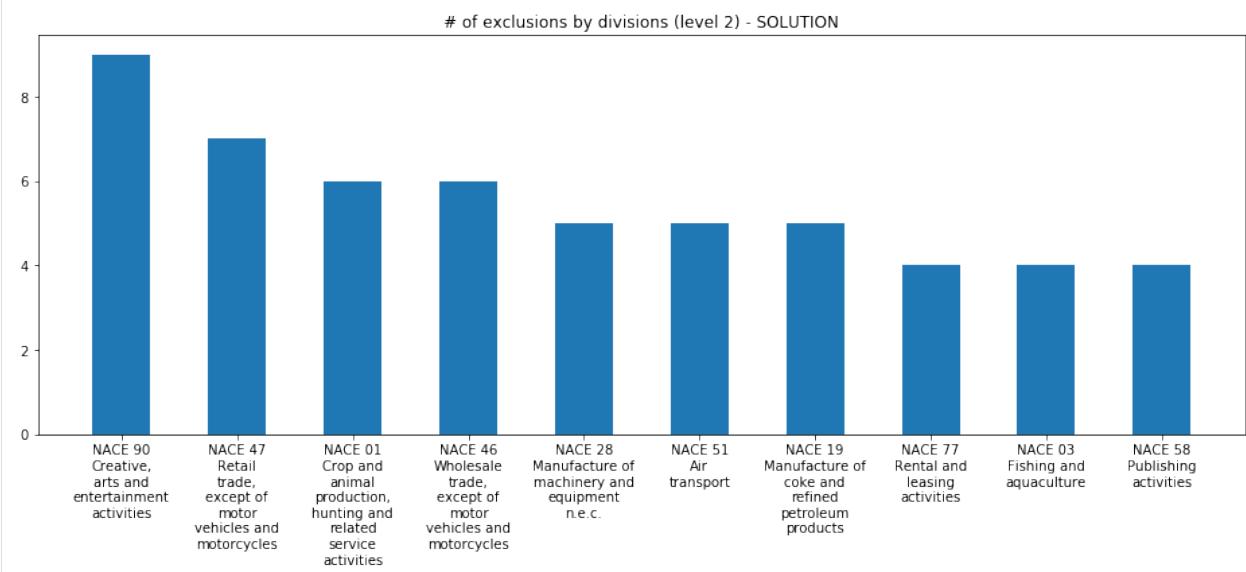

plt.xticks(xs, ['NACE ' + c[0] + '\n' + fix_label(db[c[0]]['description'])] for c
    ↵in coords)

level_names = {
    1:'Section',
    2:'division',
    3:'Group',
    4:'Class'
}
plt.title("# of exclusions by %ss (level %s) - SOLUTION" % (level_names[level],_
    ↵level))
# plt.xlabel('level_names[level]')
# plt.ylabel('y')
fig.tight_layout()
plt.savefig('division-exclusions-solution.png')
plt.show()

#Uncomment *only* if you had problems with build_db
#from expected_db import activities_db

#1 Section
#2 Division
#3 Group
#4 Class
plot(activities_db, 2)

```

</div>

[8]: %matplotlib inline

(continues on next page)

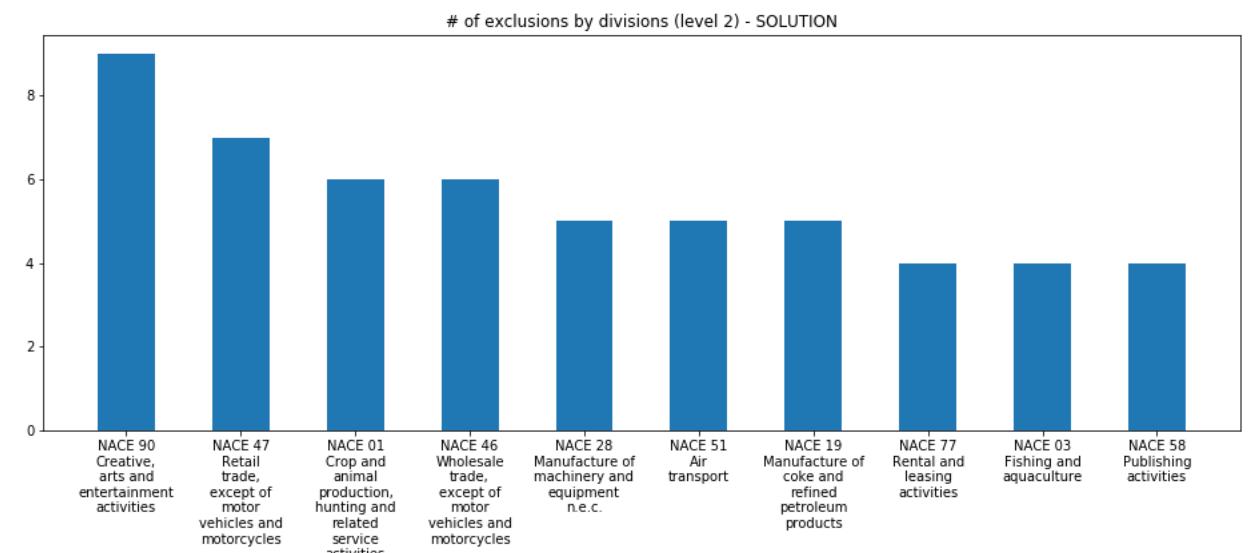

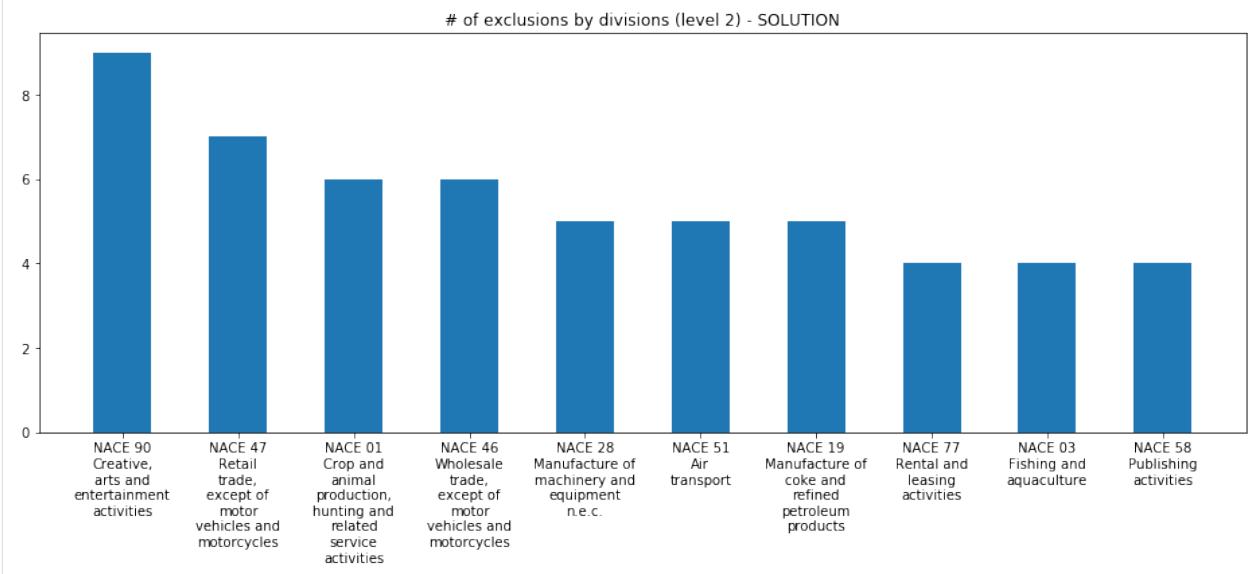

(continued from previous page)

```
def plot(db, level):

    import matplotlib.pyplot as plt
    raise Exception('TODO IMPLEMENT ME !')

#Uncomment *only* if you had problems with build_db
#from expected_db import activities_db

#1 Section
#2 Division
#3 Group
#4 Class
plot(activities_db, 2)
```

Part B

B1 Theory

Write the solution in separate theory.txt file

B1.1 complexity

Given a list L of n elements, please compute the asymptotic computational complexity of the following function, explaining your reasoning.

```
def my_fun(L):
    n = len(L)
    if n <= 1:
        return 1
    else:
        L1 = L[0:n//2]
        L2 = L[n//2:]
        a = my_fun(L1) + min(L1) - n
        b = my_fun(L2) + min(L2) - n
        return a + b
```

B1.2 describe

Briefly describe what a hash table is and provide an example of its usage.

B2 - OfficeQueue

An office offers services 'x', 'y' and 'z'. When people arrive at the office, they state which service they need, get a ticket and enqueue. Suppose at the beginning of the day we are considering there is only one queue.

The office knows on average how much time each service requires:

```
[9]: SERVICES = { 'x':5,    # minutes
                  'y':20,
                  'z':30
                }
```

With this information it is able to inform new clients approximately how long they will need to wait.

OfficeQueue is implemented as a linked list, where people enter the queue from the tail and leave from the head. We can represent it like this (NOTE: 'cumulative wait' is not actually stored in the queue):

```
wait time: 155 minutes

cumulative wait:  5    10    15    45    50    55    85    105   110   130   150   155
wait times:      5      5      5     30      5      5     30     20      5     20     20      5
                 x      x      x      z      x      x      z      y      x      y      y      x
                 a -> b -> c -> d -> e -> f -> g -> h -> i -> l -> m -> n
                           ^                               ^
                           |                               |
                           head                           tail
```

Each node holds the client identifier 'a', 'b', 'c', and the service label (like 'x') requested by the client:

```
class Node:
    def __init__(self, initdata, service):
        self._data = initdata
        self._service = service
        self._next = None
```

OfficeQueue keeps fields `_services`, `_size` and a field `_wait_time` which holds the total wait time of the queue:

```
class OfficeQueue:
    def __init__(self, services):
        self._head = None
        self._tail = None
        self._size = 0
        self._wait_time = 0
        self._services = dict(services)
```

```
[10]: from office_queue_sol import *
SERVICES = { 'x':5,      # minutes
            'y':20,
            'z':30
        }

oq = OfficeQueue(SERVICES)
print(oq)
```

OfficeQueue:

```
[11]: oq.enqueue('a', 'x')
oq.enqueue('b', 'x')
oq.enqueue('c', 'x')
oq.enqueue('d', 'z')
oq.enqueue('e', 'x')
oq.enqueue('f', 'x')
oq.enqueue('g', 'z')
oq.enqueue('h', 'y')
oq.enqueue('i', 'x')
oq.enqueue('l', 'y')
oq.enqueue('m', 'y')
oq.enqueue('n', 'x')
```

```
[12]: print(oq)

OfficeQueue:
  x      x      x      z      x      x      z      y      x      y      y      x
  a -> b -> c -> d -> e -> f -> g -> h -> i -> l -> m -> n
```

```
[13]: oq.size()
[13]: 12
```

Total wait time can be accessed from outside with the method `wait_time()`:

```
[14]: oq.wait_time()
```

```
[14]: 155
```

ATTENTION: you only need to implement the methods `time_to_service` and `split`

DO NOT touch other methods.

B2.1 - `time_to_service`

Open file `office_queue_exercise.py` with and start editing.

In order to schedule work and pauses, for each service office employees want to know after how long they will have to process the first client requiring that particular service.

First service encountered will always have a zero time interval (in this example it's x):

```
wait time: 155

cumulative wait:  5    10    15    45    50    55    85    105   110   130   150   155
wait times:      5     5     5    30     5     5    30    20     5    20    20    20     5
                  x     x     x     z     x     x     z     y     x     y     y     x
                  a -> b -> c -> d -> e -> f -> g -> h -> i -> l -> m -> n
                  ||           |           |
                  x : 0         |         |
                  |           |           |
                  |-----|           |
                  |       z : 15       |
                  |           |           |
                  |-----|           |
                  y : 85
```

```
[15]: SERVICES = { 'x':5,    # minutes
                  'y':20,
                  'z':30
                }
```

```
oq = OfficeQueue(SERVICES)
print(oq)
```

```
OfficeQueue:
```

```
[16]: oq.enqueue('a', 'x')
oq.enqueue('b', 'x')
oq.enqueue('c', 'x')
oq.enqueue('d', 'z')
oq.enqueue('e', 'x')
oq.enqueue('f', 'x')
oq.enqueue('g', 'z')
oq.enqueue('h', 'y')
oq.enqueue('i', 'x')
oq.enqueue('l', 'y')
oq.enqueue('m', 'y')
```

(continues on next page)

(continued from previous page)

```
oq.enqueue('n', 'x')

print(oq)

OfficeQueue:
    x      x      x      z      x      x      z      y      x      y      y      x
    a -> b -> c -> d -> e -> f -> g -> h -> i -> l -> m -> n
```

Method to implement will return a dictionary mapping each service to the time interval after which the service is first required:

```
[17]: oq.time_to_service()

[17]: {'x': 0, 'y': 85, 'z': 15}
```

Services not required by any client

As a special case, if a service is not required by any client, its time interval is set to the queue total wait time (because a client requiring that service might still show up in the future and get enqueued)

```
[18]: oq = OfficeQueue(SERVICES)
oq.enqueue('a', 'x')      # completed after 5 mins
oq.enqueue('b', 'y')      # completed after 5 + 20 mins
print(oq)

OfficeQueue:
    x      y
    a -> b
```

```
[19]: print(oq.wait_time())

25
```

```
[20]: oq.time_to_service()      # note z is set to total wait time

[20]: {'x': 0, 'y': 5, 'z': 25}
```

Now implement this:

```
def time_to_service(self):
    """ RETURN a dictionary mapping each service to the time interval after which
        the service is first required.

        - the first service encountered will always have a zero time interval
        - If a service is not required by any client, time interval is set to
          the queue total wait time
        - MUST run in O(n) where n is the size of the queue.
    """
```

Testing: python3 -m unittest office_queue_test.TestTimeToService

B2.2 split

Suppose a new desk is opened: to reduce waiting times the office will communicate on a screen to some people in the current queue to move to the new desk, thereby creating a new queue. The current queue will be split in two according to this criteria: after the cut, the total waiting time of the current queue should be the same or slightly bigger than the waiting time in the new queue:

ATTENTION: This example is **different** from previous one (total wait time is 150 instead of 155)

ORIGINAL QUEUE:

```
wait time = 150 minutes
wait time / 2 = 75 minutes

cumulative wait: 30 50 80 110 115 120 140 145 150
wait times:      30 20 30 30 5   5   20 5   5
                  z   y   z   z   x   x   y   x   x
                  a -> b -> c -> d -> e -> f -> g -> h -> i
                  ^           ^
                  |           |
head          cut here          tail
```

MODIFIED QUEUE:

```
wait time: 80 minutes

wait times:      30 20 30
cumulative wait: 30 50 80
                  z   y   z
                  a -> b -> c
                  ^           ^
                  |           |
head          tail
```

NEW QUEUE:

```
wait time: 75 minutes

wait times:      30 5   5   20   5   5
cumulative wait: 30 35 40 60 65 70
                  z   x   x   y   x   x
                  d -> e -> f -> g -> h -> i
                  ^           ^
                  |           |
head          tail
```

Implement this method:

```
def split(self):
    """ Perform two operations:
        - MODIFY the queue by cutting it so that the wait time of this cut
          will be half (or slightly more) of wait time for the whole original queue
```

(continues on next page)

(continued from previous page)

- RETURN a NEW queue holding remaining nodes after the cut - the wait time of new queue will be half (or slightly less) than original wait time
 - If queue to split is empty or has only one element, modify nothing and RETURN a NEW empty queue
 - After the call, present queue wait time should be equal or slightly bigger than returned queue.
 - DO *NOT* create new nodes, just reuse existing ones
 - REMEMBER to set _size, _wait_time, _tail in both original and new queue
 - MUST execute in O(n) where n is the size of the queue
- """

Testing: python3 -m unittest office_queue_test.SplitTest

[]:

2.1.16 Exam - Mon 24, Aug 2020

Scientific Programming - Data Science @ University of Trento

Download exercises and solutions

Introduction

- Taking part to this exam erases any vote you had before

What to do

- 1) Download sciprog-ds-2020-08-24-exam.zip and extract it on your desktop. Folder content should be like this:
- 2) Rename sciprog-ds-2020-08-24-FIRSTNAME-LASTNAME-ID folder: put your name, lastname and id number, like sciprog-ds-2020-08-24-john-doe-432432

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins. If it takes longer, leave it and try another exercise.
- 4) When done:
 - if you have unitn login: zip and send to examina.icts.unitn.it/studente¹¹⁶
 - If you don't have unitn login: tell instructors and we will download your work manually

¹¹⁶ <http://examina.icts.unitn.it/studente>

Part A - Prezzario

Open Jupyter and start editing this notebook exam-2020-08-24.ipynb

You are going to analyze the dataset EPPAT-2018-new-compact.csv, which is the price list for all products and services the Autonomous Province of Trento may require. Source: dati.trentino.it¹¹⁷

DO NOT WASTE TIME LOOKING AT THE WHOLE DATASET!

The dataset is quite complex, please focus on the few examples we provide

We will show examples with pandas, but it is not required to solve the exercises.

```
[1]: import pandas as pd
import numpy as np

pd.set_option('display.max_colwidth', -1)

df = pd.read_csv('EPPAT-2018-new-compact.csv', encoding='latin-1')
```

The dataset contains several columns, but we will consider the following ones:

```
[2]: df = df[['Codice Prodotto', 'Descrizione Breve Prodotto', 'Categoria', 'Prezzo']]
df[:22]

[2]:      Codice Prodotto          Descrizione Breve Prodotto \
0    A.02.35.0050    ATTREZZATURA PER INFISSEGNAZIONE PALI PILOTI
1    A.02.35.0050.010  Attrezzatura per infissione pali piloti.
2    A.02.40          ATTREZZATURE SPECIALI
3    A.02.40.0010      POMPA COMPLETA DI MOTORE
4    A.02.40.0010.010  fino a mm 50.
5    A.02.40.0010.020  oltre mm 50 fino a mm 100.
6    A.02.40.0010.030  oltre mm 100 fino a mm 150.
7    A.02.40.0010.040  oltre mm 150 fino a mm 200.
8    A.02.40.0010.050  oltre mm 200.
9    A.02.40.0020      GRUPPO ELETTRICO
10   A.02.40.0020.010  fino a 10 KW
11   A.02.40.0020.020  oltre 10 fino a 13 KW
12   A.02.40.0020.030  oltre 13 fino a 20 KW
13   A.02.40.0020.040  oltre 20 fino a 28 KW
14   A.02.40.0020.050  oltre 28 fino a 36 KW
15   A.02.40.0020.060  oltre 36 fino a 56 KW
16   A.02.40.0020.070  oltre 56 fino a 80 KW

Pompa completa a motore Example

If we look at the dataset, in some cases we can spot a pattern like the following (rows 3 to 8 included):

[3]:	df[3:12]				
	Codice Prodotto	Descrizione Breve Prodotto	Breve Prodotto	Categoria	Prezzo
3	A.02.40.0010	POMPA COMPLETA DI MOTORE		NaN	NaN
4	A.02.40.0010.010	fino a mm 50.		Noli e trasporti	2.21
5	A.02.40.0010.020	oltre mm 50 fino a mm 100.		Noli e trasporti	3.36
6	A.02.40.0010.030	oltre mm 100 fino a mm 150.		Noli e trasporti	4.42
7	A.02.40.0010.040	oltre mm 150 fino a mm 200.		Noli e trasporti	5.63
8	A.02.40.0010.050	oltre mm 200.		Noli e trasporti	6.84
9	A.02.40.0020	GRUPPO ELETTROGENO		NaN	NaN
10	A.02.40.0020.010	fino a 10 KW		Noli e trasporti	8.77
11	A.02.40.0020.020	oltre 10 fino a 13 KW		Noli e trasporti	9.94

We see the first column holds product codes. If two rows share a code prefix, they belong to the same product type. As an example, we can take product A.02.40.0010, which has 'POMPA COMPLETA A MOTORE' as description ('Descrizione Breve Prodotto' column). The first row is basically telling us the product type, while the following rows are specifying several products of the same type (notice they all share the A.02.40.0010 prefix code until 'GRUPPO ELETTROGENO' excluded). Each description specifies a range of values for that product: *fino a* means *until to*, and *oltre* means *beyond*.

Notice that:

- first row has only one number
- intermediate rows have two numbers
- last row of the product series (row 8) has only one number and contains the word *oltre* (*beyond*) (in some other cases, last row of product series may have two numbers)

A1 extract_bounds

Write a function that given a Descrizione Breve Prodotto **as a single string** extracts the range contained within as a tuple.

If the string contains only one number n:

- if it contains UNTIL (‘fino’) it is considered a first row with bounds (0 , n)
- if it contains BEYOND (‘oltre’) it is considered a last row with bounds (n , math.inf)

DO NOT use constants like measure units ‘mm’, ‘KW’, etc in the code

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

data-jupman-show="Show solution"

data-jupman-hide="Hide">Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[4]: import math

#use this list to remove unneeded stuff
PUNCTUATION=[',','`','-','.',':','%']
UNTIL = 'fino'
BEYOND = 'oltre'

def extract_bounds(text):

    fixed_text = text
    for pun in PUNCTUATION:
        fixed_text = fixed_text.replace(pun, ' ')
    words = fixed_text.split()
    i = 0
    left = None
    right = None

    while i < len(words) and (not left or not right):

        if words[i].isdigit():
            if not left:
                left = int(words[i])
            elif not right:
                right = int(words[i])
        i += 1

    if not right:
        if BEYOND in text:
            right = math.inf
        else:
            right = left
            left = 0

    return (left,right)

assert extract_bounds('fino a mm 50.') == (0,50)
assert extract_bounds('oltre mm 50 fino a mm 100.') == (50,100)
assert extract_bounds('oltre mm 200.') == (200, math.inf)
assert extract_bounds('da diametro 63 mm a diametro 127 mm') == (63, 127)
assert extract_bounds('fino a 10 KW') == (0,10)
assert extract_bounds('oltre 156 fino a 184 KW') == (156,184)
```

(continues on next page)

(continued from previous page)

```

assert extract_bounds('fino a 170 A, avviamento elettrico') == (0, 170)
assert extract_bounds('oltre 170 A fino a 250 A, avviamento elettrico') == (170, 250)
assert extract_bounds('oltre 300 A, avviamento elettrico') == (300, math.inf)
assert extract_bounds('tetti piani o con bassa pendenza - fino al 10%') == (0, 10)
assert extract_bounds('tetti a media pendenza - oltre al 10% e fino al 45%') == (10,
    ↵45)
assert extract_bounds('tetti ad alta pendenza - oltre al 45%') == (45, math.inf)

```

</div>

[4]: import math

```

#use this list to remove unneeded stuff
PUNCTUATION=[' ',',','-','.','%']
UNTIL = 'fino'
BEYOND = 'oltre'

def extract_bounds(text):
    raise Exception('TODO IMPLEMENT ME !')

assert extract_bounds('fino a mm 50.') == (0,50)
assert extract_bounds('oltre mm 50 fino a mm 100.') == (50,100)
assert extract_bounds('oltre mm 200.') == (200, math.inf)
assert extract_bounds('da diametro 63 mm a diametro 127 mm') == (63, 127)
assert extract_bounds('fino a 10 KW') == (0,10)
assert extract_bounds('oltre 156 fino a 184 KW') == (156,184)
assert extract_bounds('fino a 170 A, avviamento elettrico') == (0,170)
assert extract_bounds('oltre 170 A fino a 250 A, avviamento elettrico') == (170, 250)
assert extract_bounds('oltre 300 A, avviamento elettrico') == (300, math.inf)
assert extract_bounds('tetti piani o con bassa pendenza - fino al 10%') == (0, 10)
assert extract_bounds('tetti a media pendenza - oltre al 10% e fino al 45%') == (10,
    ↵45)
assert extract_bounds('tetti ad alta pendenza - oltre al 45%') == (45, math.inf)

```

A2 extract_product

Write a function that given a filename, a code and a unit, parses the csv until it finds the corresponding code and RETURNS **one** dictionary with relevant information for that product

- Prezzo (price) **must be converted to float**
- **implement the parsing with a** csv.DictReader, see example¹¹⁸
- **as encoding, use latin-1**

[5]: # Suppose we want to get all info about A.02.40.0010 prefix:
df[3:12]

	Codice Prodotto	Descrizione Breve Prodotto	Categoria	Prezzo
3	A.02.40.0010	POMPA COMPLETA DI MOTORE	NaN	NaN
4	A.02.40.0010.010	fino a mm 50.	Noli e trasporti	2.21
5	A.02.40.0010.020	oltre mm 50 fino a mm 100.	Noli e trasporti	3.36
6	A.02.40.0010.030	oltre mm 100 fino a mm 150.	Noli e trasporti	4.42
7	A.02.40.0010.040	oltre mm 150 fino a mm 200.	Noli e trasporti	5.63

(continues on next page)

¹¹⁸ <https://sciprog.davidleoni.it/formats/format-sol.html#Reading-as-dictionaries>

(continued from previous page)

8	A.02.40.0010.050	oltre mm 200.	Noli e trasporti	6.84
9	A.02.40.0020	GRUPPO ELETTRICO	NaN	NaN
10	A.02.40.0020.010	fino a 10 KW	Noli e trasporti	8.77
11	A.02.40.0020.020	oltre 10 fino a 13 KW	Noli e trasporti	9.94

A call to

```
pprint(extract_product('EPPAT-2018-new-compact.csv', 'A.02.40.0010', 'mm'))
```

Must produce:

```
{'category': 'Noli e trasporti',
 'code': 'A.02.40.0010',
 'description': 'POMPA COMPLETA DI MOTORE',
 'measure_unit': 'mm',
 'models': [{ 'bounds': (0, 50), 'price': 2.21, 'subcode': '010'},
             { 'bounds': (50, 100), 'price': 3.36, 'subcode': '020'},
             { 'bounds': (100, 150), 'price': 4.42, 'subcode': '030'},
             { 'bounds': (150, 200), 'price': 5.63, 'subcode': '040'},
             { 'bounds': (200, math.inf), 'price': 6.84, 'subcode': '050'}]}
```

Notice that if we append subcode to code (with a dot) we obtain the full product code.

<a class="jupman-sol" jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

A3 plot_product

Implement following function that takes a dictionary as output by previous extract_product and shows its price ranges.

- pay attention to display title and axis labels as shown, using input data and **not** constants.
- in case last range holds a `math.inf`, show a $>$ sign
- **if you don't have a working extract_product, just copy paste data from previous asserts.**

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

data-jupman-show="Show solution"

data-jupman-hide="Hide">Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[7]: %matplotlib inline

import numpy as np
import matplotlib.pyplot as plt

def plot_product(product):

    models = product['models']
    xs = np.arange(len(models))
    ys = [model["price"] for model in models]

    plt.bar(xs, ys, 0.5, align='center')

    plt.title('%s (%s) SOLUTION' % (product['description'], product['code']))

    ticks = []
    for model in models:
        bounds = model["bounds"]
        if bounds[1] == math.inf:
            ticks.append('>%s' % bounds[0])
        else:
            ticks.append('%s - %s' % (bounds[0], bounds[1]))

    plt.xticks(xs, ticks)
    plt.gcf().set_size_inches(11,8)
    plt.xlabel(product['measure_unit'])
    plt.ylabel('Price (€)')

    plt.savefig('pompa-a-motore-solution.png')
    plt.show()

product = extract_product('EPPAT-2018-new-compact.csv', 'A.02.40.0010', 'mm')
#product = extract_product('EPPAT-2018-new-compact.csv', 'A.02.40.0020', 'KW')
#product = extract_product('EPPAT-2018-new-compact.csv', 'B.02.10.0042', 'mm')
#product = extract_product('EPPAT-2018-new-compact.csv', 'B.30.10.0010', '%')

plot_product(product)
```

</div>

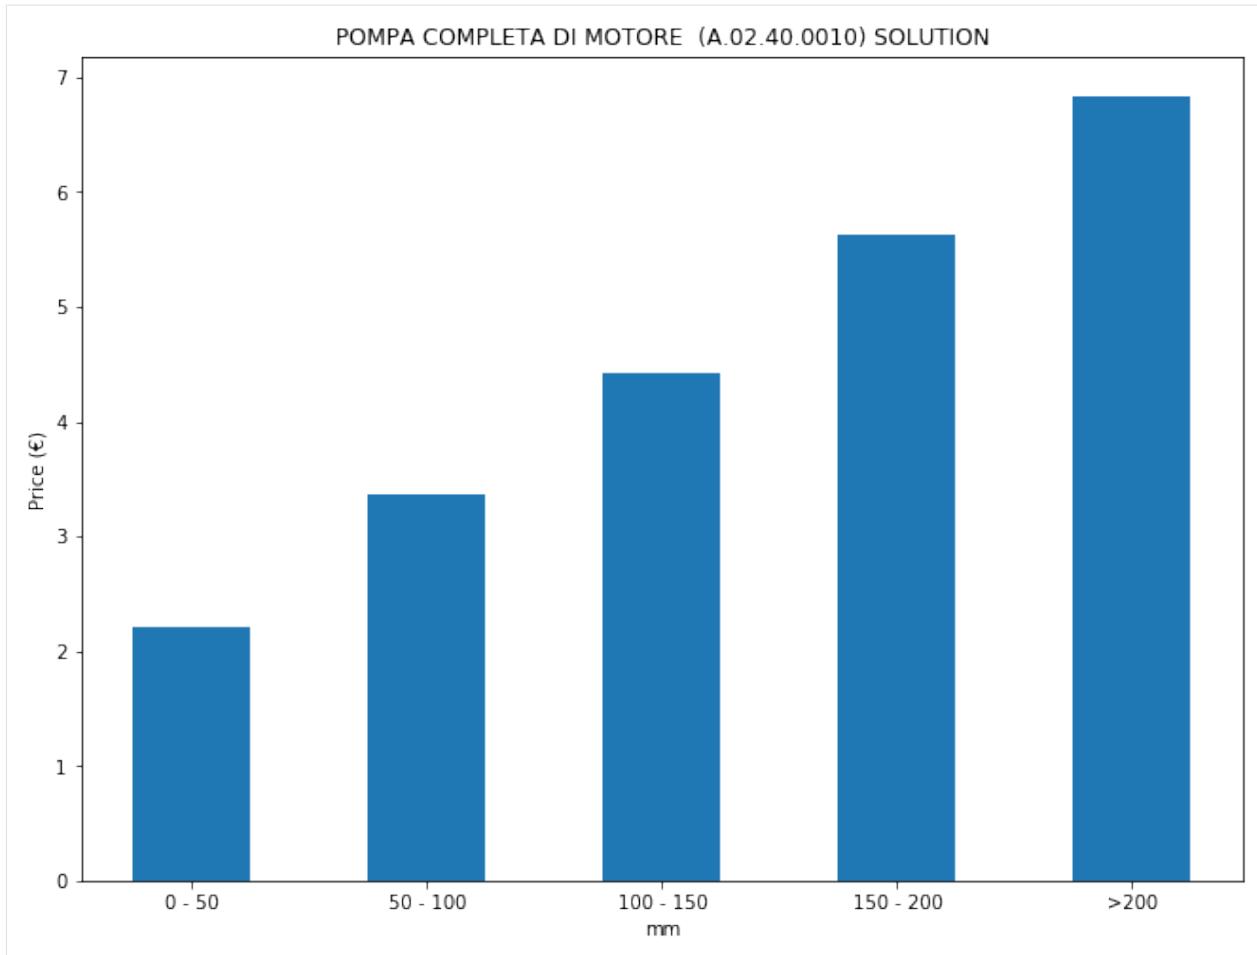

```
[7]: %matplotlib inline

plot_product(product)
```

Part B

B1 Theory

Write the solution in separate ``theory.txt`` file

B1.1 complexity

Given a list L of n elements, please compute the asymptotic computational complexity of the following function, explaining your reasoning.

```
def my_fun(L):
    n = len(L)
    tmp = []
    for i in range(int(n)):
        tmp.insert(0, L[i]-L[int(n/3)])
    return sum(tmp)
```

B1.2 describe

Briefly describe what a graph is and the two classic ways that can be used to represent it as a data structure.

B2 couple_sort

Open a text editor and edit file `linked_list.py`. Implement this method:

```
def couple_sort(self):
    """MODIFIES the linked list by considering couples of nodes at *even* indexes
       and their successors: if a node data is lower than its successor data, ↵
    ↵swaps
       the nodes *data*.

    - ONLY swap *data*, DO NOT change node links.
    - if linked list has odd size, simply ignore the exceeding node.
    - MUST execute in O(n), where n is the size of the list
    """

```

Testing: `python3 -m unittest linked_list_Test.CoupleSortTest`

Example:

```
[8]: from linked_list_sol import *
from linked_list_test import to_ll

[9]: ll = to_ll([4,3,5,2,6,7,6,3,2,4,5,3,2])

[10]: print(ll)
LinkedList: 4,3,5,2,6,7,6,3,2,4,5,3,2

[11]: ll.couple_sort()

[12]: print(ll)
LinkedList: 3,4,2,5,6,7,3,6,2,4,3,5,2
```

Notice it sorted each couple at even positions. This particular linked list has odd size (13 items), so last item 2 was not considered.

B3 schedule_rec

Suppose the nodes of a binary tree represent tasks (nodes data is the task label). Each task may have up to two subtasks, represented by its children. To be declared as completed, each task requires first the completion of all of its subtasks.

We want to create a schedule of tasks, so that to declare completed the task at the root of the tree, before all tasks below it must be completed, specifically first the tasks on the left side, and then the tasks on the right side. If you apply this reasoning recursively, you can obtain a schedule of tasks to be executed.

Open `bin_tree.py` and implement this method:

```
def schedule_rec(self):
    """ RETURN a list of task labels in the order they will be completed.

        - Implement it with recursive calls.
        - MUST run in O(n) where n is the size of the tree

        NOTE: with big trees a recursive solution would surely
              exceed the call stack, but here we don't mind
    """

```

Testing: python3 -m unittest bin_tree_test.ScheduleRecTest

Example:

For this tree, it should return the schedule ['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i']

Here we show code execution with the same tree:

```
[13]: from bin_tree_sol import *
from bin_tree_test import bt
```

```
[14]: tasks = bt('i',
                 bt('d',
                     bt('b',
                         bt('a')),
                     bt('c')),
                 bt('h',
                     bt('f',
                         None,
                         bt('e')),
                     bt('g')))
```

```
[15]: print(tasks)
```

```
i
├d
│ └b
│   └a
│   └c
└h
  └f
    └t
      └e
    └g
```

```
[16]: tasks.schedule_rec()
[16]: ['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i']
```

2.1.17 Midterm Sim - Mon 02, Nov 2020

Scientific Programming - Data Science @ University of Trento

Download exercises and solutions

This simulation gives you NO credit whatsoever: If you do everything wrong, you lose nothing. If you do everything correct, you gain nothing

What to do

- 1) Download `sciprog-ds-2020-11-02-exam.zip` and extract it on your desktop.
- 2) Rename `sciprog-ds-2020-11-02-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2020-11-02-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise. Every exercise should take max 25 mins.
If it takes longer, leave it and try another exercise.
- 4) When done:
 - if you have unitn login: zip and send to examina.icts.unitn.it/studente¹¹⁹
 - If you don't have unitn login: tell instructors and we will download your work manually

¹¹⁹ <http://examina.icts.unitn.it/studente>

Part A - Galactic Love

Open Jupyter and start editing this notebook exam-2020-11-02.ipynb

Since today is a pseudo-exam, you are going to do pseudo-science!

The company Astro Logic provides horoscopes to thousands of loyal customers, who each day require a number of divinitions. The most requested is whether or not they should engage in love affairs with a potential partner, who is chosen according to rigourous criteria like his/her astrological sign. You are then hired to devise a fancy visualization which given two astrological signs and their love compatibility, displays the constellations of their signs close when the compatibility is high and far away when compatibility is low.

parse_stars

Let's start with real astronomical data. You are given a database of constellations called stars.csv (we slightly tweaked it for this occasion - original data source: Space Telescope Science Institute¹²⁰)

```
[1]: import pandas as pd

stars_df = pd.read_csv('stars.csv', encoding='UTF-8')
stars_df[0:32]
```

	constellation	type	ra	dec	description
0	Andromeda	0	3717	2539	move gamma 1
1	Andromeda	1	2091	2137	draw beta
2	Andromeda	1	1179	1851	draw delta
3	Andromeda	1	251	1745	draw alpha
4	Andromeda	0	1716	1405	move eta
5	Andromeda	1	1420	1456	draw zeta
6	Andromeda	1	1156	1758	draw epsilon
7	Andromeda	1	1179	1851	draw delta
8	Andromeda	1	1106	2023	draw pi
9	Andromeda	1	512	2320	draw theta
10	Andromeda	1	42544	2596	draw iota
11	Andromeda	1	42612	2660	draw kappa
12	Andromeda	1	42526	2787	draw lambda
13	Andromeda	0	42544	2596	move iota
14	Andromeda	1	41457	2539	draw omicron
15	Andromeda	0	1106	2023	move pi
16	Andromeda	1	2091	2137	draw beta
17	Andromeda	1	1702	2309	draw mu
18	Andromeda	1	1494	2464	draw nu
19	Andromeda	1	2085	2834	draw phi
20	Andromeda	1	2939	2917	draw 51
21	Andromeda	-1	0	0	NaN
22	Antlia	0	17077	-2157	move epsilon
23	Antlia	2	18814	-1864	dotted alpha
24	Antlia	2	19701	-2228	dotted iota
25	Antlia	-1	0	0	NaN
26	Apus	0	26635	-4742	move alpha
27	Apus	2	29803	-4733	dotted gamma
28	Apus	2	30092	-4651	dotted beta
29	Apus	2	29410	-4721	dotted delta 1
30	Apus	2	29803	-4733	dotted gamma
31	Apus	-1	0	0	NaN

¹²⁰ https://github.com/mperrin/misc_astro

You will have to parse it so to obtain a dictionary which maps each constellation to its stars, expressed as a list of lists of points type and coordinates.

Since later we will need to show points in a 2d chart, you will have to transform the coordinates obtained from the data (right ascension and declination in degrees) as follows:

$$x = \frac{15}{1800}ra$$

$$y = \frac{dec}{60}$$

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[2]: import csv

def parse_stars(filename):

    ret = {}
    with open(filename, encoding='utf-8', newline='') as f:
        my_reader = csv.reader(f, delimiter=',')
        next(my_reader) # skips header
        constellation = ''
        d = None
        for row in my_reader:
            if row[0] != constellation:
                constellation = row[0]
                stars = []
                ret[constellation] = stars
            coords = [0]* 3
            coords[0] = int(row[1])
            coords[1] = int(row[2]) * (1.0 / 1800) * 15
            coords[2] = int(row[3]) * (1.0 / 60)
            stars.append(coords)

    return ret

stars_db = parse_stars('stars.csv')
```

</div>

```
[2]: import csv

def parse_stars(filename):
    raise Exception('TODO IMPLEMENT ME !')

stars_db = parse_stars('stars.csv')
```

You can find the complete output in `expected_stars_db.py`

plot_stars 1

Write a function `plot_stars` to plot constellations

WARNING: DO NOT use GraphViz!

Even if we are making plots which look like networks, for these visualizations you just need basic matplotlib (and some creativity ;-)

WARNING: for now, ignore the `new_center` parameter

A point type can either be:

- 0: start a new line not connected with the previous one
- 1: connect previous point with a straight segment
- 2: connect previous point with a dotted segment (draw it with `linestyle=':'` parameter)
- -1: last point, ignore

Available colorschemes are '`M`', '`F`', or '`R`' (red)

- to set a black background, set `plt.rcParams['axes.facecolor'] = 'black'`
- to get a nice glowing effect for the lines, draw twice: once with a thick line and dark color, and once with a thin line with a bright color. You can find the colors in `color_schemes`. To set them in `plt.plot` call, use `linewidth` (sets width in pixels) and `color` parameter, note `color` takes a **single** parameter
- draw stars as white dots, setting `markersize=6`

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

>Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[3]: %matplotlib inline

import numpy as np
import matplotlib.pyplot as plt

color_schemes = {
    'M': ('blue', '#039dfc'),
    'F': ('purple', 'pink'),
    'R': ('darkred', 'red')
}

def plot_stars(constellation_name, color_scheme, stars, new_center=None):

    plt.rcParams['axes.facecolor'] = 'black'

    color1, color2 = color_schemes[color_scheme]

    point_list = stars[constellation_name]
    points = np.asarray(point_list)
    drawtype = points[:,0]
    ra_degrees = points[:-1,1]
    dec_degrees = points[:-1,2]

    if new_center:
        xbounds = (np.min(ra_degrees), np.max(ra_degrees))
        ybounds = (np.min(dec_degrees), np.max(dec_degrees))
        halfx = (xbounds[1]-xbounds[0])/2
        halfy = (ybounds[1]-ybounds[0])/2

        ra_degrees -= xbounds[0] + halfx - new_center[0]
        dec_degrees -= ybounds[1] - halfy - new_center[1]

    for i in range(0, len(drawtype)-1):
        if drawtype[i] == 0 or drawtype[i] == -1:
            continue

        xs = ra_degrees[i-1:(i)+1]
        ys = dec_degrees[i-1:(i)+1]
        plt.plot(xs,ys, linewidth=8, linestyle=':' if drawtype[i] == 2 else "--", color=color1)
        plt.plot(xs,ys, linewidth=3, linestyle=':' if drawtype[i] == 2 else "--", color=color2)
        plt.plot(xs, ys, 'o', markersize=6, color='white')

plot_stars 2 - new_center

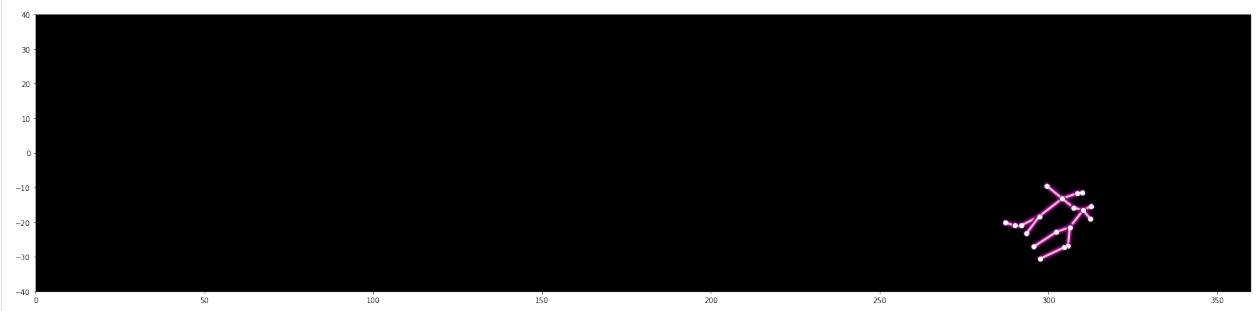

Change the previous function `plot_stars` so it accepts a new argument `new_center`, which is either `None` or a tuple of coordinates where the constellation should be centered:

- be precise in determining the boundaries of the constellation
- **DO NOT** assume the constellation has a fixed width nor height (so no constants in code!)

```
[7]: fig = plt.figure(figsize=(30,7))
plt.xlim(0,360)
plt.ylim(-40,40)
plot_stars('Gemini', 'F', stars_db, new_center=None) # no translation
```

```
[8]: fig = plt.figure(figsize=(30,7))
plt.xlim(0,360)
plt.ylim(-40,40)
plot_stars('Gemini', 'F', stars_db, new_center=(300, -20)) # centered in 300, -20
```

parse_zodiac

You are given a file `zodiac.csv`. For each sign, the table contains astrological information and affinity with other signs, expressed as a relation matrix:

```
[9]: import pandas as pd
df = pd.read_csv('zodiac.csv', encoding='UTF-8')
df[:4]
```

	Constellation	House	Glyph	Symbol	Dates	Element	\
0	Aries	1	♈	Ram	21 March\n-\n20 April	Fire	
1	Taurus	2	♉	Bull	21 April\n-\n21 May	Earth	
2	Gemini	3	♊	Twins	22 May\n-\n21 June	Air	
3	Cancer	4	♋	Crab	22 June\n-\n21 July	Water	

	Quality	Ruling	Planet	Day/Night	Aries	...	Gemini	Cancer	Leo	\
0	Cardinal		Mars	Day	NaN	...	4.0	NaN	5.0	
1	Fixed		Venus	Night	NaN	...	NaN	4.0	NaN	
2	Mutable		Mercury	Day	4.0	...	NaN	NaN	4.0	
3	Cardinal		Moon	Night	NaN	...	NaN	NaN	NaN	

	Virgo	Libra	Scorpius	Sagittarius	Capricornus	Aquarius	Pisces
0	NaN	NaN	NaN	5.0	NaN	4.0	NaN
1	5.0	NaN	NaN	NaN	5.0	NaN	4.0
2	NaN	5.0	NaN	NaN	NaN	5.0	NaN
3	4.0	NaN	5.0	NaN	NaN	NaN	5.0

[4 rows x 21 columns]

Parse the table so to get a a dictionary of dictionaries, with some selected data:

- affinities are in the scale 1-5, normalize them to floats 0.0-1.0
- dates contain \n , normalize them so to have dates separated by a dash as in 21 March–20 April

NOTE: To parse the file, a `csv.reader` is sufficient, it's not necessary to use pandas - even if data seem to span multiple lines because of the \n in dates, note they are bounded by " so rows will be correctly parsed by `csv.reader`

You can find the complete output in `expected_zodiac_db.py`

```
{
    'Aquarius': {
        'affinities': {

```

plot_love

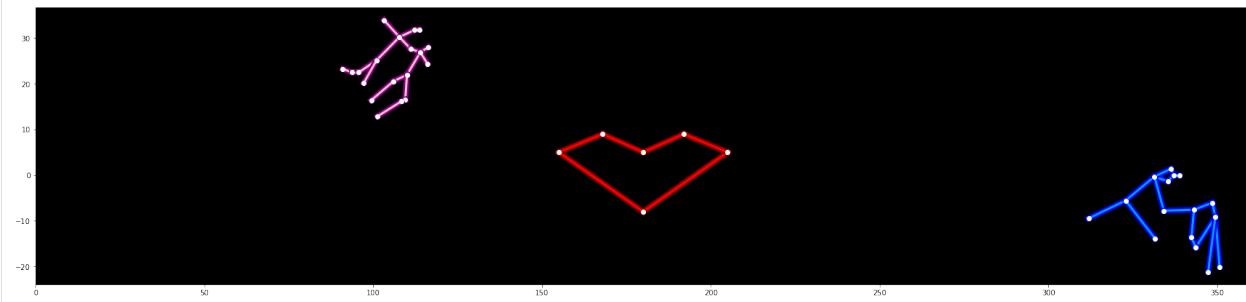

In stars.csv we inserted the special (fake!) constellation of 'Love': given the importance, we placed it at the center of the galaxy, positioned at x=180 degrees and y=0. If you try to plot it now, you should get something like this:

```

[11]: # 'Aries',    'Taurus',    'Gemini',      'Cancer',      'Leo',       'Virgo',
# 'Libra',    'Scorpius',   'Sagittarius', 'Capricornus', 'Aquarius',  'Pisces'

fig = plt.figure(figsize=(30,7))
plt.xlim(0,360)
plot_stars('Gemini','F', stars_db)
plot_stars('Aquarius','M', stars_db)
plot_stars('Love','R', stars_db)    # fake!

```

Given two astrological signs, place them on the same y=0 axis as the heart and make them symmetrically closer or farther from it according to their astrological affinity, also displaying their name and astrological glyph:

- **REMEMBER** title and xlabel !
- you can reuse previosly defined `plot_stars` function
- constellations x centers should go from 50 to 150 degrees (and symmetrically, from -50 to -150)
- **BUT you will have to display reversed ticks:** 100 50 0 for positive (and symmetrically 0 50 100 for negative)

For drawing text:

- For increasing text size in `title`, `xticks`, `xlabel`, `text` calls, you can use `fontsize=20` parameter (for glyphs you will need a bigger number)
- for text inside the chart use `plt.text(x, y, "some text")`
- the glyph must be drawn bigger than the sign name, so you will need a separate call to `plt.text`

2.1.18 Midterm A - Fri 06, Nov 2020

Scientific Programming - Data Science @ University of Trento

Download exercises and solutions

Taking part to this exam erases any vote you had before

- 1) Download `sciprog-ds-2020-11-06-exam.zip` and extract it on your desktop.
- 2) Rename `sciprog-ds-2020-11-06-FIRSTNAME-LASTNAME-ID` folder: put your name, lastname and id number, like `sciprog-ds-2020-11-06-john-doe-432432`

From now on, you will be editing the files in that folder. At the end of the exam, that is what will be evaluated.

- 3) Edit the files following the instructions in this worksheet for each exercise.
- 4) When done zip and send to examina.icts.unitn.it/studente¹²¹

Music Sequencer

Open Jupyter and start editing this notebook `exam-2020-11-06.ipynb`

`ABC`¹²² is a popular format to write music notation in plain text files, you can see an example by opening `tunes.abc` with a text editor. A music sequencer is an editor software which typically displays notes as a matrix: you will parse simplified abc tunes and display their melodies in a matrix.

1. parse_melody

Write a function which given a melody as a string of notes translates it to a list of tuples:

```
>>> parse_melody(" |A4      C2  E2 |C4      E D C2 |C3      B3      G2 | ")
[(0, 8), (2, 4), (4, 4), (2, 8), (4, 2), (3, 2), (2, 4), (2, 6), (1, 6), (6, 4)]
```

Each melody note is followed by its duration. If no duration number is specified, we assume it is one.

Each tuple first element represents a note as a number from 0 (A) to 6 (G) and the second element is the note length in the sequencer. We assume our sequencer has a resolution of two beats per note, so for us a note A would have length 2, a note A2 a length 4, a note A3 a length 6 and so on.

- DO NOT care about spaces nor bars |, they have no meaning at all
- To get a character position, use `ord` python function

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

[1]:

```
def parse_melody(melody):

    notes = melody.replace(' | ', ' ').split()

    ret = []
    for note in notes:
        n = ord(note[0]) - ord('A')
```

[(0, 8), (2, 4), (4, 4), (2, 8), (4, 2), (3, 2), (2, 4), (2, 6), (1, 6), (6, 4)]

```

2. parse_tunes

An .abc file is a series of key:value fields. Keys are always one character long. Anything after a % is a comment and must be ignored

File tunes.abc excerpt:

```
[2]: with open("tunes.abc", encoding='utf-8') as f: print(''.join(f.readlines()[0:17]))  
  
%abc-2.1  
H:Tune made in a dark algorithmic night      % history and origin in header, so  
→replicated in all tunes!  
O:Trento  
  
X:1          % index  
T:Algorave   % title  
C:The Lord of the Loop % composer  
M:4/4        % meter  
K:C          % key  
|A4    C2  E2 |C4    E D C2 |C3     B3     G2 |    % melodies can also have a comment  
  
X:2  
T:Transpose Your Head  
C:Matrix Queen  
M:3/4  
K:G  
|F2  G4    |E4    E F |A2  B2  D2 |D3    E3    |C3    C3 |
```

First lines (3 in the example) are the file header, separated by tunes with a blank line.

- first line must always be ignored
- fields specified in the file header must be copied in *all* tunes

After the first blank line, there is the first tune:

- X is the tune index, convert it to integer
- M is the meter, convert it to a tuple of two integers
- K is the last field of metadata
- melody line has no field key, it always follows line with K and it immediately begins with a pipe: convert it to list by calling `parse_melody`

Following tunes are separated by blank lines

Write a function `parse_tunes` which parses the file and outputs a list of dictionaries, one per tune. Use provided `field_names` to obtain dictionary keys. Full expected db is in `expected_db.py` file.

DO NOT write hundreds of ifs

Special keys are listed above, all others should be treated in a generic way

DO NOT assume header always contains 'origin' and 'history'

It can contain *any* field, which has to be then copied in all the tunes.

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```

```

3. sequencer

Write a function `sequencer` which takes a melody in text format and outputs a matrix of note events, as a list of strings. The rows are all the notes on keyboard (we assume 7 notes without black keys) and the columns represent the duration of a note.

- a note start is marked with < character, a sustain with = character and end with >
 - **HINT 1:** call `parse_melody` to obtain notes as a list of tuples (if you didn't manage to implement it copy expected list from `expected_db.py`)
 - **HINT 2:** build first a list of list of characters, and only at the very end convert to a list of strings
 - **HINT 3:** try obtaining the note letters for first column by using `ord` and `chr`

```
<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);>Show solution</a><div class="jupman-sol jupman-sol-code" style="display:none">
```

```
[5]: def sequencer(melody):

    notes = parse_melody(melody)
    length = 0
    for note in notes:
        length += note[1]
    ret = []

    work = [' ']*(length+1) for i in range(7)]
    for i in range(7):
        work[i][0] = chr(ord('A')+i)

    j = 0
    for n,d in notes:
        work[n][j+1] = '<'
        eqlen = d-2
        work[n][j+2 : j+eqlen+2] = '=' * eqlen # cool slice writing
        work[n][j+d] = '>'
        j += d
    return ''.join(w) for w in work]

from pprint import pprint
melody1 = "A4          C2  E2 | C4          E  D  C2 | C3          B3      G2  | "
exp1 = [
    'A<=====>',
    ',
```

(continues on next page)

(continued from previous page)

```
'B          <==>      <=====>      <==><=====>      <=====>      '
'C          <==>      <=====>      <==><=====>      <=====>      '
'D          <==>      <=====>      <>          <=====>      '
'E          <==>      <=====>      <>          <=====>      '
'F          <=====>      <=====>      <=====>      <=====>      '

res2 = sequencer(melody2)
print(' ' + melody2)
print()
pprint(res2)
assert res2 == exp2
|F2 G4 |E4 E F|A2 B2 D2 |D3 E3 |C3 C3 |
[ 'A' <==> 'B' <==> 'C' <=====><=====> 'D' <=====><=====> 'E' <=====><> 'F<==>' <=====> 'G' <=====> ' '

```

4. plot_tune

Make it fancy: write a function which takes a tune dictionary from the db and outputs a plot

- use beats as xs, remembering the shortest note has two beats
- to increase thickness, use linewidth=5 parameter

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

data-jupman-show="Show solution"

data-jupman-hide="Hide">Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

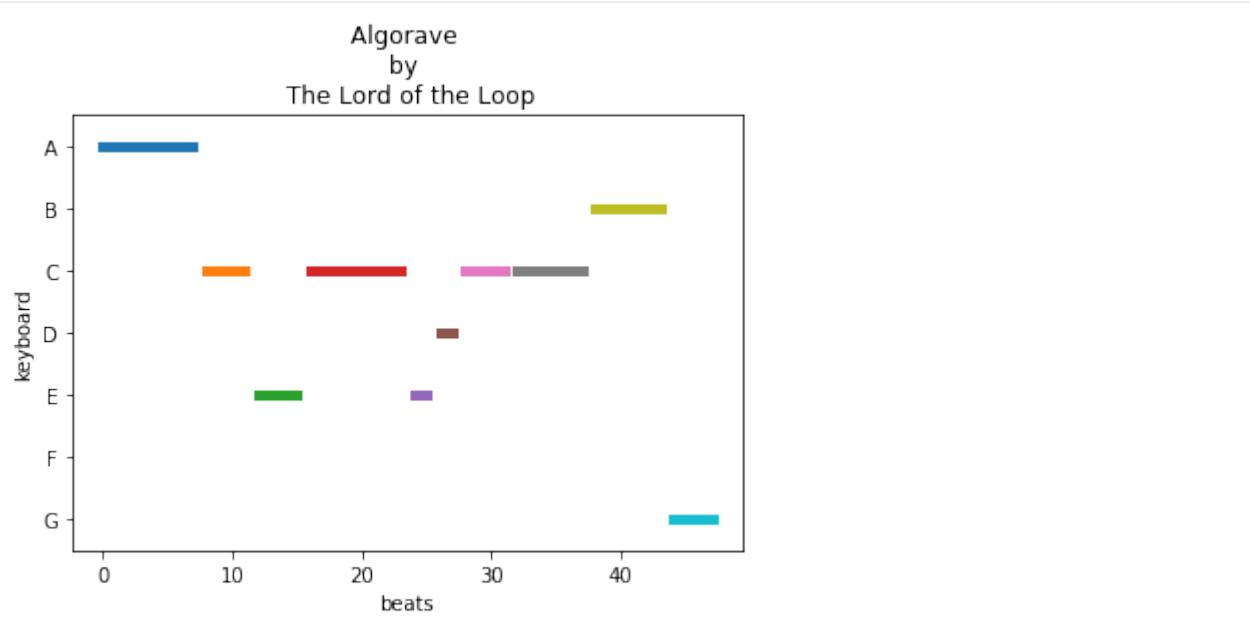

```
[7]: %matplotlib inline
import matplotlib.pyplot as plt

def plot_tune(tune):

    j = 0
    for n,d in tune['melody']:
        r = 6 - n
        xs = [j, j+d-1]
        ys = [r, r]
        j += d
        plt.plot(xs, ys, linewidth=5)

    plt.title('%s \nby \n %s' %(tune['title'], tune['composer']))
    plt.ylim(-0.5,6.5)
    plt.yticks(range(7), [chr(ord('G')-i) for i in range(7)])
    plt.xlabel('beats')
    plt.ylabel('keyboard')

plot_tune(tunes_db[0])
```

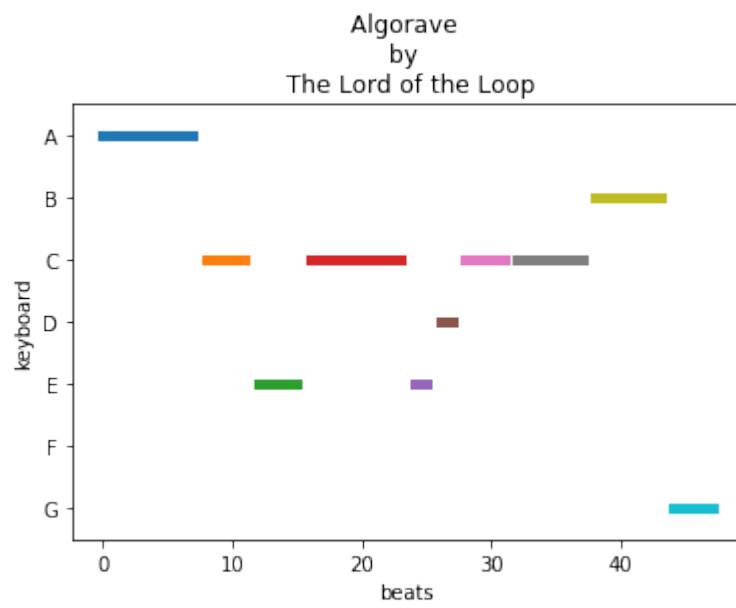

</div>

```
[7]: %matplotlib inline
import matplotlib.pyplot as plt

def plot_tune(tune):
    raise Exception('TODO IMPLEMENT ME !')

plot_tune(tunes_db[0])
```

[]:

2.2 2017-18 (QCB)

See QCB master past exams on [sciprolab2 Github](#)¹²³

NOTE: Those exams are useful, but for you there will be:

- no biological examples
- less dynamic programming
- more exercises on graphs & matrices
- exercise on pandas
- custom DiGraph won't have Visit and VertexLog classes

2.3 2016-17 (QCB)

See [davidleoni.github.io/algolab/past-exams.html](#)¹²⁴

WARNING: keep in mind that 2016-17 exams are for Python 2 - in this course we use Python 3

[] :

¹²³ https://github.com/DavidLeoni/sciprolab2/tree/master/overlay/_static

¹²⁴ <https://davidleoni.github.io/algolab/past-exams.html>

old 2019/20 slides

3.1 Part A

3.2 Lab A.1

Wednesday 23 Sep 2020

3.2.1 Links

lab site: sciprog.davidleoni.it¹²⁵

- *Installation* from sciprog, with links to relevant SoftPython stuff
- Tools and Scripts on SoftPython¹²⁶ : describes Jupyter and other things are described more in detail
- Python basics¹²⁷ : hopefully we will see something (try doing them at home anyway)

What I expect

- if you don't program in Python, you don't learn Python
- you don't learn Python if you don't program in Python
- to be a successful data scientist, you must know programming
- **Exercise:** now put the right priorities in your TODO list ;-)

¹²⁵ <https://sciprog.davidleoni.it>

¹²⁶ <https://en.softpython.org/tools/tools-sol.html>

¹²⁷ <https://en.softpython.org/basics/basics-sol.html>

Course contents

- Hands-on approach

Part A - python intro

- logic basics
- discrete structures basics
- python basics
- data cleaning
- format conversion (matrices, tables, graphs, ...)
- visualization (matplotlib, graphviz)
- some analytics (with pandas)
- focus on correct code, don't care about performance
- plus: some software engineering wisdom

Part A exams:

There will always be some practical structured exercise.

Examples:

- analyzing employees of University of Trento¹²⁸
- visualizing intercity bus network¹²⁹
- extracting categories from workshops of Trentino¹³⁰

Sometimes, there can also be a more abstract thing with matrices / relations, (i.e. surjective relation¹³¹)

DO read the exam rules¹³²

Part B - algorithms

- going from theory taught by Prof. Luca Bianco to Python 3 implementation
- performance matters
- few Python functions

3.3 Lab A.2

Monday 28 Sep 2020

Worksheets

- *Finish Basics* (NOTE: redownload it, was updated)
- Strings1 - Introduction¹³³
- Strings2 - Operators¹³⁴

¹²⁸ <https://sciprog.davidleoni.it/exams/2019-08-26/solutions/exam-2019-08-26-sol.html#Part-A---University-of-Trento-staff>

3.4 Lab A.3

Wednesday 30 Set 2020

Worksheets:

- Lists1 - Introduction¹³⁸
- Lists2 - Operators¹³⁹
- Lists3 - Methods¹⁴⁰
- (a fourth page remains to be added)

References: Andrea Passerini - data structures slides¹⁴¹

For Realtime stuff during the lab, see this repl:

<https://repl.it/@DavidLeoniWork/sciprog-ds-lab-2020-21>

3.5 Lab A.4

Monday 5 Oct 2020

Worksheets (now English links are finally online!)

- Tuples¹⁴²
- Sets¹⁴³
- Dictionaries1 - Introduction¹⁴⁴
- Dictionaries2 - Operators¹⁴⁵
- Dictionaries3 - Methods¹⁴⁶
- (a fourth and fifth pages remain to be added)

References:

- Real Python sets¹⁴⁸

For realtime stuff during the lab, see this repl:

<https://repl.it/@DavidLeoniWork/sciprog-ds-lab-2020-21>

I copy here last weekend announcement:

I added here some links to exercises: <https://en.softpython.org/references.html>

- Beginners: try W3Resources
- Intermediate: exercises from LeetCode and first tutorial from Software Carpentry
- Math-oriented people: try Introduction to Scientific Programming with Python by Joakim Sundnes

3.6 Lab A.5

Wednesday 7 Oct 2020

- Worksheets (now English links are finally online!)
 - Control Flow 1 - ifs¹⁴⁹
 - Control Flow 2 - for¹⁵⁰
 - Control Flow 3 - while¹⁵¹
 - Errors and testing¹⁵² Note: SoftPython tutorial only talks about quick testing with assert which is fine for Part A of this course. In Part B we will use more sophisticated testing with unittest
 - References: Andrea Passerini - complex statements¹⁵³

For realtime stuff during the lab, see this repl:

<https://repl.it/@DavidLeoniWork/sciprog-ds-lab-2020-21>

3.7 Lab A.6

Monday 12 Oct 2020

Worksheets

- More on functions
- Matrices - list of lists¹⁵⁴
- Errors and testing¹⁵⁵ Note: SoftPython tutorial only talks about quick testing with assert which is fine for Part A of this course. In Part B we will use more sophisticated testing with unittest

References:

For realtime stuff during the lab, see this repl:

<https://repl.it/@DavidLeoniWork/sciprog-ds-lab-2020-21>

3.8 Lab A.7

Wednesday 14 Oct 2020

Worksheets

- Sequences¹⁵⁸ (already translated)
- Data formats¹⁵⁹ (already translated)

References:

- Andrea Passerini - Modules and programs¹⁶⁰

For realtime stuff during the lab, see this repl:

<https://repl.it/@DavidLeoniWork/sciprog-ds-lab-2020-21>

3.9 Lab A.8

Monday 19 Oct 2020

Worksheets:

- Graph formats¹⁶¹
 - graph matrices, adjacency lists (we will use networkx next lab)
- Binary relations¹⁶² (finish at home)

NOTE: In Part A we will limit ourselves to graph formats and see some theory in separate binary relations notebook, while in Part B of the course will focus on graph algorithms¹⁶³

For realtime stuff during the lab:

- sciprog repl¹⁶⁴
- graphviz repl¹⁶⁵
- graph drawings and challenges¹⁶⁶

3.9.1 How to see graphviz on repl.it

Since we're online, I came up with this solution

NOTE: this is a shaky experiment only to share code during the lab, but you won't need if you do the worksheets above alone.

1. Go to this NEW repl: <https://repl.it/@DavidLeoniWork/softgraphviz>
2. Fork the project (**DO NOT** copy paste files in your projects, you **really** need to fork !)

3. Run the script - you will have to wait some time until it loads all the packages:

NOTE: this will activate a *server*, which means from now on the server will be kept running and you shouldn't need to click on Run again (unless of course something is seriously compromised)

https://SurprisedOptimalPatches--five-nine.repl.co

example.py Reload

gravizo

```

graph TD
    0((0)) -- "1" --> 1((1))
    0 -- "1" --> 1
    0 -- "1" --> 1
    1 -- "1" --> 0
    1 -- "1" --> 0
    1 -- "1" --> 0
  
```

* Serving Flask app "soft" (lazy loading)
 * Environment: production
 WARNING: Do not use the development server in a production environment.
 Use a production WSGI server instead.
 * Debug mode: off
 * Running on http://0.0.0.0:8080/ (Press CTRL+C to quit)
 The module is 'example.py'
 Dot saved to file: output.dot
 Dot saved to file: output.dot
 172.18.0.1 - - [19/Oct/2020 10:27:57] "GET / HTTP/1.1" 200 -

4. Try making changes to `example.py` and then, instead of hitting the usual Run in repl, click the Reload button. Reload will run the script `example.py`, which at the end regenerates the `output.dot` file used in the visualization

NOTE: that after a while of inactivity, the server might stop and repl will need to reload all the packages.

```

example.py
1
2 # notice links with weight zero are not shown)
3 # all weights are set to 1
4
5 import sys
6 from soft import draw_mat
7
8 mat = [
9     [1,0,0,1], # node 0 is linked to node 0 itself,
10    node 1 and node 2
11    [1,1,1,0], # node 1 is linked to node 2 and node 3
12    [1,0,1,1], # node 2 is linked to node 0, node 1,
13    node 2 itself and node 3
14    [0,0,0,1] # node 3 is linked to node 1 and node
15    ]
16
17 # !!! IMPORTANT !!!:
18 # for viz_server to work, you have to add
19 #           save_to='output.dot'
20 #
21 draw_mat(mat, save_to='output.dot')

```

3.10 Lab A.9

Wednesday 21 Oct 2020

EXAM - Save the date:

- Simulation: Monday 2 November, 14:30-16:30 (online)
- Midterm Part A: Friday 6 November, 11:30-13:30 (online) - please login 15 mins before and allocate some time after the end in case we have technical problems

Simulation attendance is recommended!: during the simulation and the exam you will connect online to a linux environment (but you **do not** need to install linux!), so the simulation is your chance to try the system.

You will receive official communication with details in a short time. For now **please read** exam guidelines from previous years¹⁶⁷

WORKSHEETS:

Today we focus on graphs as adjacency lists, networkx

- Graph formats¹⁶⁸
- Binary relations¹⁶⁹

NOTE: In Part A we will limit ourselves to graph formats and see some theory in separate binary relations notebook, while in Part B of the course will focus on **graph algorithms**¹⁷⁰

¹⁶⁷ <https://sciprog.davidleoni.it/#Exams>

¹⁶⁸ <https://en.softpython.org/graph-formats/graph-formats-sol.html>

¹⁶⁹ <https://en.softpython.org/binary-relations/binary-relations-sol.html>

¹⁷⁰ <https://sciprog.davidleoni.it/graph-algos/graph-algos.html>

For realtime stuff during the lab:

- sciprog repl¹⁷¹
- graphviz repl¹⁷² (to use, see instructions of *previous lab*)
- graph drawings and challenges¹⁷³

3.11 Lab A.10

Monday 26 Oct 2020

Worksheets:

Today we focus on numpy and matplotlib

- Matrices - Numpy¹⁷⁴ - actually we don't do that much of numpy, it's more an introduction to things needed for visualization
- Visualization with matplotlib¹⁷⁵
- The AlgoRhythm Opera Challenge¹⁷⁶

NOTE 1: Visualization worksheet is different from Italian version! Contains also some statistics on networks.

NOTE 2: after the lab I put on softpython a revised version of the The AlgoRhythm Opera Challenge. In particular even if you were at the lab, make sure to try [this new last part of the challenge¹⁷⁷](#), with changed variables: most probably you will discover there is some constant in your code which should be a variable instead.

References:

- Andrea Passerini Numpy and Matplotlib slides¹⁷⁸

For realtime stuff during the lab:

- sciprog repl¹⁷⁹
- graph drawings and challenges¹⁸⁰

3.12 Lab A.11

Wednesday 28 Oct 2020

Worksheets:

- Matrices - Numpy images (new!)¹⁸¹ - was proposed as a challenge during the lab, now on the website you can find a revised version with solutions. Notice images may look like an application, but actually they are matrices, only much nicer to see!

References:

For realtime stuff during the lab:

- sciprog repl¹⁸³
- graph drawings and challenges¹⁸⁴

3.13 Lab A.12

Wednesday 4 Nov 2020

Worksheets:

- Pandas tutorial¹⁸⁵
- Pandas case study: EURES job offers¹⁸⁶
- Pandas: Italian Poets challenge¹⁸⁷
- Exercises from Edabit, I put a selection on SoftPython References page¹⁸⁸ (if you don't see it refresh the page with ctrl-R or ctrl-F5)

Note there won't be pandas during midterm for part A, at most I will use it only to show some data. For you, it could be useful to quickly gain an understanding of dataset contents.

References:

- Andrea Passerini Pandas slides¹⁸⁹

For realtime stuff during the lab:

3.14 Part B

3.15 Lab B.1

Monday 9 Nov 2020

- Remember that from now on we only use Visual Studio Code, possibly with the Live Share extension, so get familiar with it by reading *installation*
- *Testing with unittest*
- *OOP* (probably only first part)

3.16 Lab B.2

Wednesday 11 Nov 2020

Worksheets:

- *OOP* Finished ComplexNumber, try doing Multiset on your own.
- *OOP Matrix Challenge*: (updated after the lab, please use this version). Try solving this for next week. Tests are not provided, you are invited to collaboratively write at least some in the new 'REPL Test Playground'. You can access the link on Moodle¹⁹²

¹⁹² <https://didatticaonline.unitn.it/dol/mod/url/view.php?id=721545>

3.17 Lab B.3

Monday 16 Nov 2020

Worksheets:

- Complexity: the invisible enemy
- *Sorting Challenge*
- *Sorting* Selection sort and Insertion sort

3.18 Lab B.4

Wednesday 18 Nov 2020

Worksheets:

- Complexity: the invisible enemy
- *Sorting Challenge* - I added Partitocracy challenge (a kind of quicksort)
- *Sorting* in lab we will see quicksort and mergesort, finish the rest at home

3.19 Lab B.5

Monday 23 November

- *LinkedList v1*
- *Little LinkedList challenge*

At home: try to finish whole LinkedList worksheet

3.20 Lab B.6

Wednesday 25 November

- *LinkedList v2* , other linked lists exercises
- *Stacks*

At home: try to finish whole LinkedList and stacks worksheets

3.21 Lab B.7

Monday 30 November

- *Queues* (CircularQueue and ItalianQueue)
- I added some exercises about linked lists and queues on *Part B References* page on Sciprog

At home: try to finish whole Queues worksheet

3.22 Lab B.8

Wednesday 2 December

- *Binary trees*

At home: try to finish whole Binary trees worksheet

[] :

COMMANDMENTS

4.1 MOVED TO <https://en.softpython.org/commandments.html>

You will be redirected in 10 seconds

[]:

**CHAPTER
FIVE**

6.1 Installation

You will need to install several pieces of software to get a working Python 3 programming environment. In this section we will install everything that we are going to need in the next few weeks.

There are many ways to write and execute Python code:

- Python interpreter¹⁹³ (command line)
- Visual Studio Code¹⁹⁴ (editor, good debugger)
- Jupyter¹⁹⁵ (notebook, good for experimentation and writing reports)
- Google Colab¹⁹⁶ (online, sort-of collaborative)
- repl.it¹⁹⁷ (online, collaborative)
- Python Tutor¹⁹⁸ (online, visual debugger, only for short code)

Python 3 is available for Windows, Mac and Linux. Python3 alone is often not enough, and you will need to install extra system-specific libraries + editors like Jupyter for Part A of the course and Visual Studio Code for Part B.

To avoid hassles, especially on Win / Mac you should install some so called *package manager* (Linux distributions already come with a package manager). Among the many options for this course we use the package manager Anaconda for Python 3.8

1. Install [Anaconda for Python 3.8](#)¹⁹⁹ (anaconda installer will ask you to install also visual studio code, so accept the kind offer)
2. If you didn't in the previous point, install now Visual Studio Code, which is available for all platforms. You can read about it [here](#)²⁰⁰. Downloads for all platforms can be found [here](#)²⁰¹
3. Now you can read all of [Installation on SoftPython](#)²⁰² EXCEPT:
 - For Mac users: for this course you **don't** need to install homebrew, just install Anaconda
 - For everybody: You don't need to read *Projects with virtual environments* paragraph (although it's certainly useful when you have many Python projects on your pc!)

¹⁹³ <https://www.python.org/>

¹⁹⁴ <https://code.visualstudio.com/>

¹⁹⁵ <https://jupyter.org/>

¹⁹⁶ <https://colab.research.google.com/>

¹⁹⁷ <https://repl.it/languages/python3>

¹⁹⁸ <http://www.pythontutor.com/visualize.html#mode=edit>

¹⁹⁹ <https://www.anaconda.com/download/>

²⁰⁰ <https://code.visualstudio.com/>

²⁰¹ <https://code.visualstudio.com/Download>

²⁰² <https://en.softpython.org/installation.html>

4. **Jupyter and course material format** is described in detail in Tools and Scripts on SoftPython²⁰³, read it!
5. Finally, you can get familiar with Visual Studio Code by reading what follows. Even if we will use it only in Part B, read it anyway as it's useful for many development tasks and supports a lot languages.

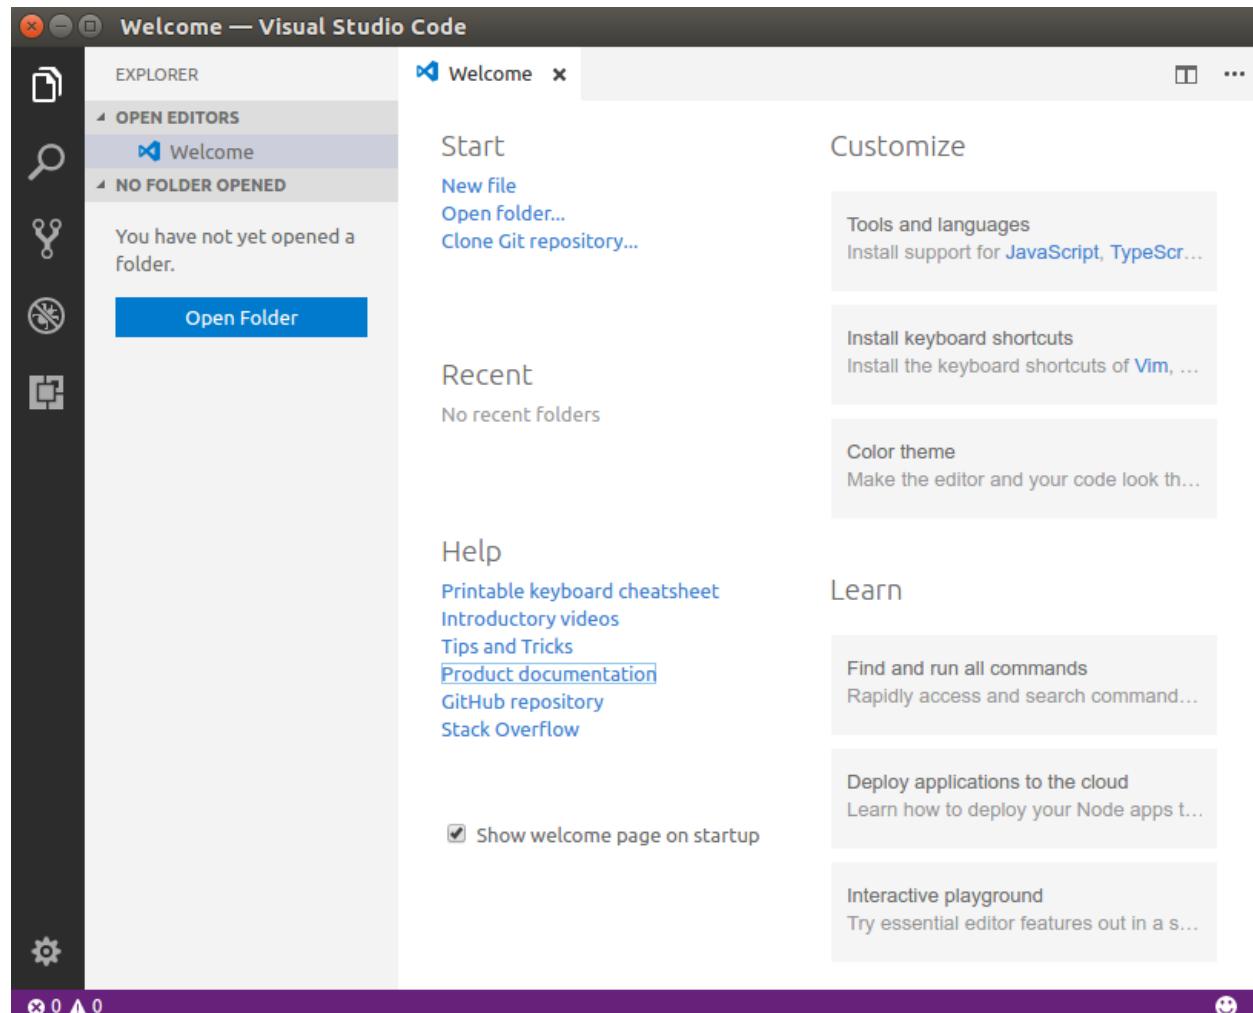

6.1.1 Visual Studio Code

Visual Studio Code²⁰⁴ is an Integrated Development Editor (IDE) for text files. It can handle many languages, Python included (python programs are text files ending in .py).

Features:

- open source
- lightweight
- used by many developers
- Python plugin is not the best, but works enough for us

Once you open the IDE Visual Studio Code you will see the welcome screen:

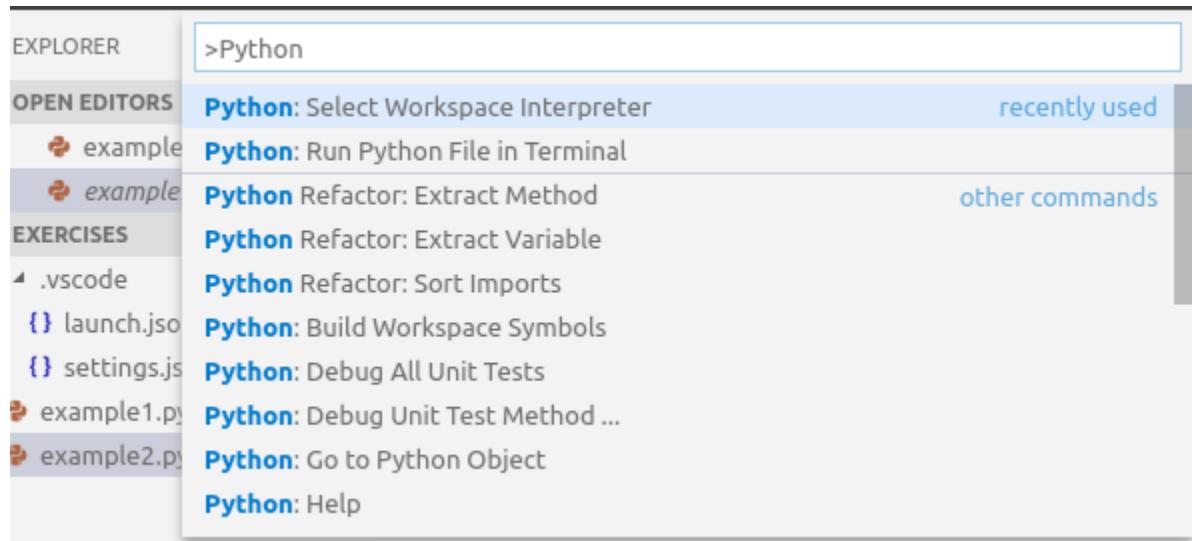

²⁰³ <https://en.softpython.org/tools/tools-sol.html>

²⁰⁴ <https://code.visualstudio.com/>

You can find useful information on this tool [here²⁰⁵](#). Please spend some time having a look at that page.

Once you are done with it you can close this window pressing on the “x”. First thing to do is to set the python interpreter to use. Click on View → Command Palette and type “Python” in the text search space. Select **Python: Select Workspace Interpreter** as shown in the picture below.

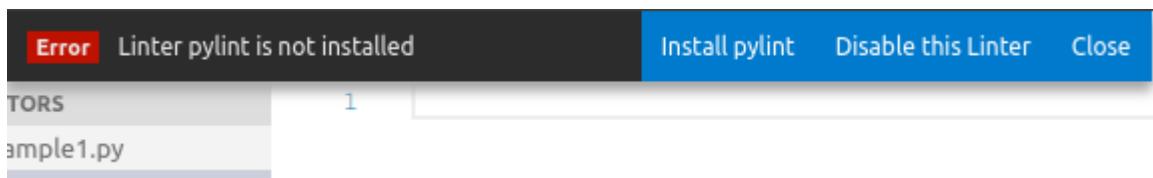

Finally, select the Python version you want to use (e.g. Python3).

Now you can click on **Open Folder** to create a new folder to place all the scripts you are going to create. You can call it something like “exercises”. Next you can create a new file, *example1.py* (.py extension stands for python).

Visual Studio Code will understand that you are writing Python code and will help you with valid syntax for your program.

Warning:

If you get the following error message:

click on **Install Pylint** which is a useful tool to help your coding experience.

Add the following text to your *example1.py* file.

```
[1]: """
This is the first example of Python script.
"""

a = 10 # variable a
b = 33 # variable b
c = a / b # variable c holds the ratio

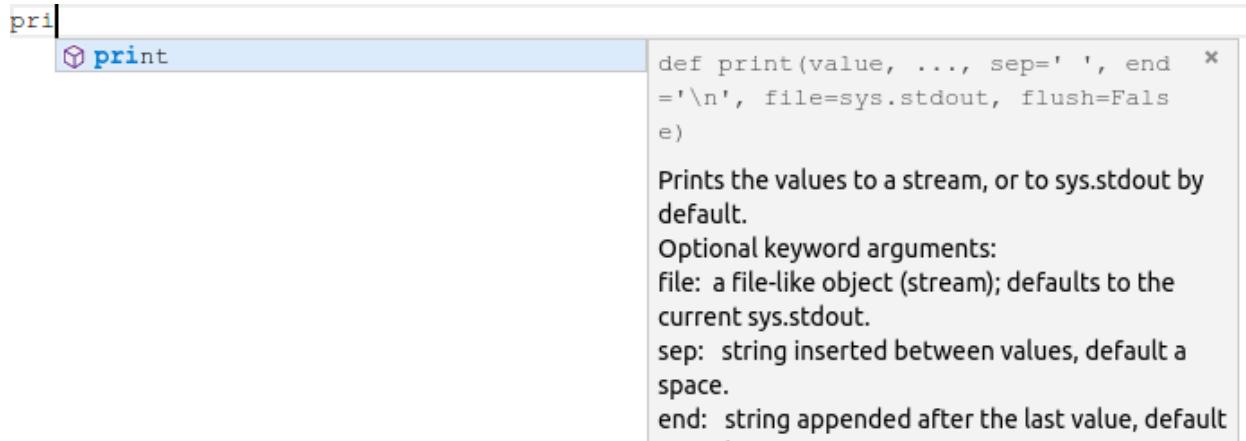

# Let's print the result to screen.
print("a:", a, " b:", b, " a/b=", c)
```

²⁰⁵ <https://code.visualstudio.com/docs#vscode>

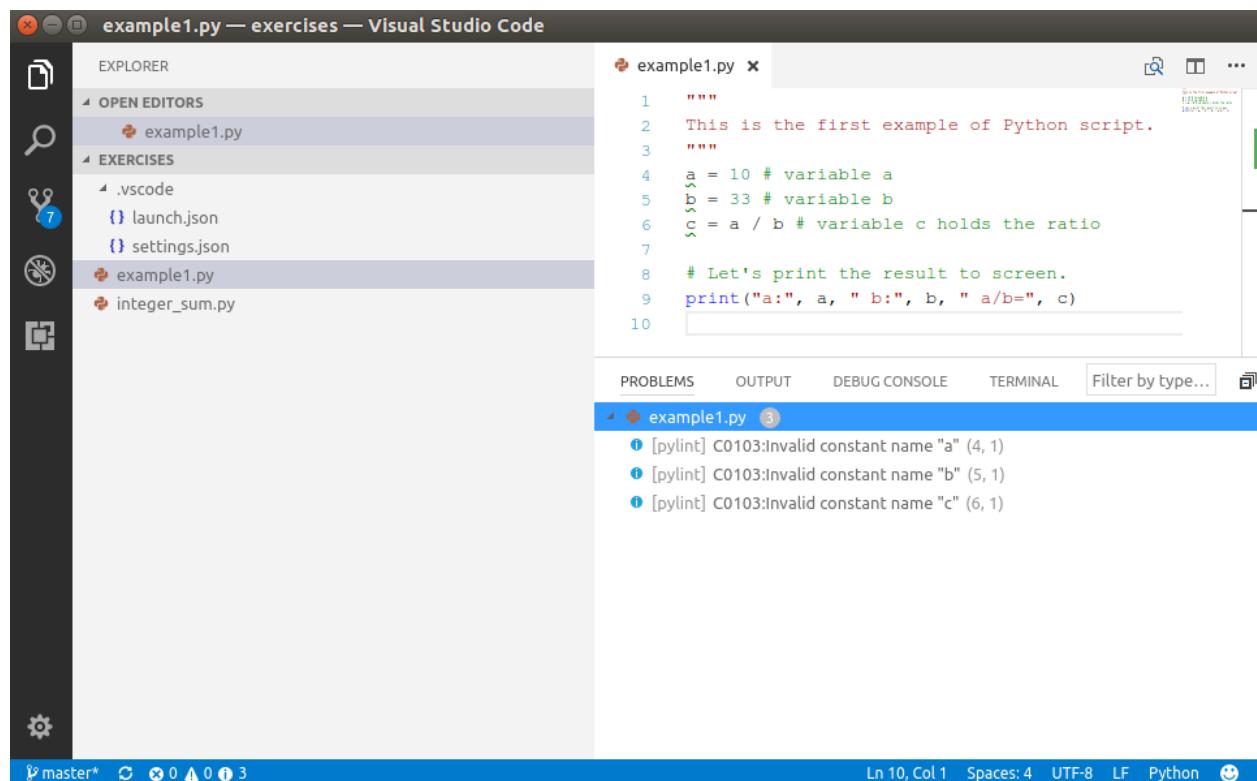

```
a: 10  b: 33  a/b= 0.30303030303030304
```

A couple of things worth nothing. The first three lines opened and closed by " " " are some text describing the content of the script. Moreover, comments are proceeded by the hash key (#) and they are just ignored by the python interpreter. **Please remember to comment your code, as it helps readability and will make your life easier when you have to modify or just understand the code you wrote some time in the past.**

Please notice that Visual Studio Code will help you writing your Python scripts. For example, when you start writing the **print** line it will complete the code for you (**if the Pylint extension mentioned above is installed**), suggesting the functions that match the letters written. This useful feature is called *code completion* and, alongside suggesting possible matches, it also visualizes a description of the function and parameters it needs. Here is an example:

Save the file (Ctrl+S as shortcut). It is convenient to ask the IDE to highlight potential *syntactic* problems found in the code. You can toggle this function on/off by clicking on **View → Problems**. The *Problems* panel should look like this

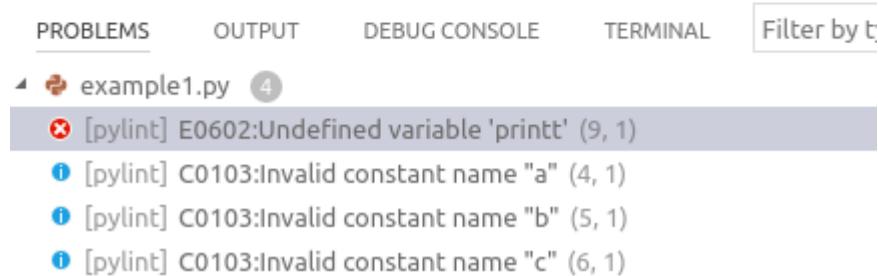

Visual Studio Code is warning us that the variable names *a,b,c* at lines 4,5,6 do not follow Python naming conventions for constants. This is because they have been defined at the top level (there is no structure to our script yet) and therefore are interpreted as constants. The naming convention for constants states that they should be in capital letters. To amend the code, you can just replace all the names with the corresponding capitalized name (i.e. A,B,C). If you do that, and you save the file again (Ctrl+S), you will see all these problems disappearing as well as the green underlining of the variable names. If your code does not have an empty line before the end, you might get another warning “*Final new line missing*”. Note that these were just warnings and the interpreter **in this case** will happily and correctly execute the code anyway, but it is always good practice to understand what the warnings are telling us before deciding to ignore them!

Had we by mistake misspelled the *print* function name (something that should not happen with the code completion tool that suggests functions names!) writing *printt* (note the double t), upon saving the file, the IDE would have underlined in red the function name and flagged it up as a problem.

```

1  """
2  This is the first example of Python script.
3  """
4  a = 10 # variable a
5  b = 33 # variable b
6  c = a / b # variable c holds the ratio
7
8  # Let's print the result to screen.
9  printt("a:", a, " b:", b, " a/b=", c)
10

```

This is because the builtin function *printt* does not exist and the python interpreter does not know what to do when it reads it. Note that *printt* is actually underlined in red, meaning that there is an error which will cause the interpreter to stop the execution with a failure. **Please remember that before running any piece of code all errors must be fixed.**

Now it is time to execute the code. By right-clicking in the code panel and selecting **Run Python File in Terminal** (see picture below) you can execute the code you have just written.

```

"""
This is the first example of Python script.

"""

a = 10 # variable a
b = 33 # variable b
c = a / b # variable c holds the ratio

# Let's print the result to screen.
print("a:", a, " b:", b, " a/b=", c)

```

Upon clicking on *Run Python File in Terminal* a terminal panel should pop up in the lower section of the coding panel and the result shown above should be reported.

Saving script files like the *example1.py* above is also handy because they can be invoked several times (later on we will learn how to get inputs from the command line to make them more useful...). To do so, you just need to call the python interpreter passing the script file as parameter. From the folder containing the *example1.py* script:

```
python3 example1.py
will in fact return:
a: 10 b: 33 a/b= 0.30303030303030304
```

Before ending this section, let me add another note on errors. The IDE will diligently point you out *syntactic* warnings and errors (i.e. errors/warnings concerning the structure of the written code like name of functions, number and type of parameters, etc.) but it will not detect *semantic* or *runtime* errors (i.e. connected to the meaning of your code or to the value of your variables). These sort of errors will most probably make your code crash or may result in unexpected results/behaviours. In the next section we will introduce the debugger, which is a useful tool to help detecting these errors.

Before getting into that, consider the following lines of code (do not focus on the *import* line, this is only to load the mathematics module and use its method *sqrt*):

```
[2]: """
Runtime error example, compute square root of numbers
"""

import math

A = 16
B = math.sqrt(A)
C = 5*B
print("A:", A, " B:", B, " C:", C)

#D = math.sqrt(A-C) # whoops, A-C is now -4!!!
#print(D)
A: 16  B: 4.0  C: 20.0
```

If you add that code to a Python file (e.g. `sqrt_example.py`), you save it and you try to execute it, you should get an error message as reported above. You can see that the interpreter has happily printed off the value of A,B and C but then stumbled into an error at line 9 (math domain error) when trying to compute $\sqrt{A - C} = \sqrt{-4}$, because the `sqrt` method of the math module cannot be applied to negative values (i.e. it works in the domain of real numbers).

Please take some time to familiarize with Visual Studio Code (creating files, saving files etc.) as in the next practicals we will take this ability for granted.

6.1.2 The debugger

Another important feature of advanced Integrated Development Environments (IDEs) is their debugging capabilities. Visual Studio Code comes with a debugging tool that can help you trace the execution of your code and understand where possible errors hide.

Write the following code on a new file (let's call it `integer_sum.py`) and execute it to get the result.

```
[3]: """ integer_sum.py is a script to
       compute the sum of the first 1200 integers. """
S = 0
for i in range(0, 1201):
    S = S + i

print("The sum of the first 1200 integers is: ", S)
```

The sum of the first 1200 integers is: 720600

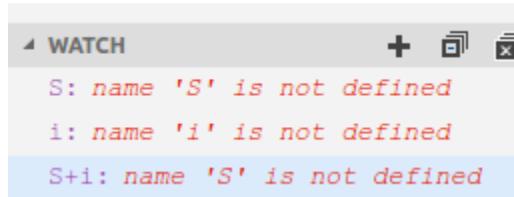

Without getting into too many details, the code you just wrote starts initializing a variable `S` to zero, and then loops from 0 to 1200 assigning each time the value to a variable `i`, accumulating the sum of `S + i` in the variable `S`. **A final thing to notice is indentation.** In Python it is important to indent the code properly as this provides the right scope for variables (e.g. see that the line `S = S + 1` starts more to the right than the previous and following line – this is because it is inside the for loop). You do not have to worry about this for the time being, we will get to this in a later practical...

How does this code work? How does the value of `S` and `i` change as the code is executed? These are questions that can be answered by the debugger.

To start the debugger, click on **Debug -> Start Debugging** (shortcut F5). The following small panel should pop up:

We will use it shortly, but before that, let's focus on what we want to track. On the left hand side of the main panel, a *Watch* panel appeared. This is where we need to add the things we want to monitor as the execution of the program goes. With respect to the code written above, we are interested in keeping an eye on the variables `S`, `i` and also of the expression `S+i` (that will give us the value of `S` of the next iteration). Add these three expressions in the watch panel (click on `+` to add new expressions). The watch panel should look like this:

do not worry about the message “*name X is not defined*”, this is normal as no execution has taken place yet and the interpreter still does not know the value of these expressions.

The final thing before starting to debug is to set some breakpoints, places where the execution will stop so that we can check the value of the watched expressions. This can be done by hovering with the mouse on the left of the line number. A small reddish dot should appear, place the mouse over the correct line (e.g. the line corresponding to `S = S + 1` and click to add the breakpoint (a red dot should appear once you click).

```

 1 """ integer_sum.py is a script to
 2     compute the sum of the first 1200 integers. """
 3
 4 S = 0
 5 for i in range(0, 1201):
 6     S = S + i
 7
 8 print("The sum of the first 1200 integers is: ", S)
 9

```

Now we are ready to start debugging the code. Click on the green triangle on the small debug panel and you will see that the yellow arrow moved to the breakpoint and that the watch panel updated the value of all our expressions.

DEBUG ▶ Python ▾ ⚙️
integer_sum.py ×
⋮ ⏪ ⏴ ⏵ ⏹ ⏺ ⏻ ⏻

VARIABLES

- Local
 - __name__: '__main__'
 - __doc__: 'integer_sum.py is ...'
 - __package__: None
 - __loader__: None
 - __spec__: None
 - __file__: '/home/biancol/Goog...'
 - __cached__: None
- builtins: {'ArithmeticErr...'}
 - S: 0
 - i: 0
 - S+i: 0

WATCH

- S: 0
- i: 0
- S+i: 0

The value of all expressions is zero because the debugger stopped **before** executing the code specified at the breakpoint line (recall that `S` is initialized to 0 and that `i` will range from 0 to 1200). If you click again on the green arrow, execution will continue until the next breakpoint (we are in a for loop, so this will be again the same line - trust me for the time being).

```

DEBUG ▶ Python ⚙ 🌐
integer_sum.py ✘ ... ► ⏪ ⏴ ⏵ ⏹ ⏺ 🔍 🔒
VARIABLES
Local
__name__: '__main__'
__doc__: 'integer_sum.py is ...
__package__: None
__loader__: None
__spec__: None
__file__: '/home/biancol/Goog...
__cached__: None
builtins: {'Arithmeti...
S: 0
...
WATCH
S: 0
i: 1
S+i: 1

```

```

1 """ integer_sum.py is a script to
2     compute the sum of the first 1200 integers. """
3
4 S = 0
5 for i in range(0, 1201):
6     S = S + i
7
8 print("The sum of the first 1200 integers is: ", S)
9

```

Now `i` has been increased to 1, `S` is still 0 (remember that the execution stopped **before** executing the code at the breakpoint) and therefore `S + i` is now 1. Click one more time on the green arrow and values should update accordingly (i.e. `S` to 1, `i` to 2 and `S + i` to 3), another round of execution should update `S` to 3, `i` to 3 and `S + i` to 6. Got how this works? Variable `i` is increased by one each time, while `S` increases by `i`. You can go on for a few more iterations and see if this makes any sense to you, once you are done with debugging you can stop the execution by pressing the red square on the small debug panel.

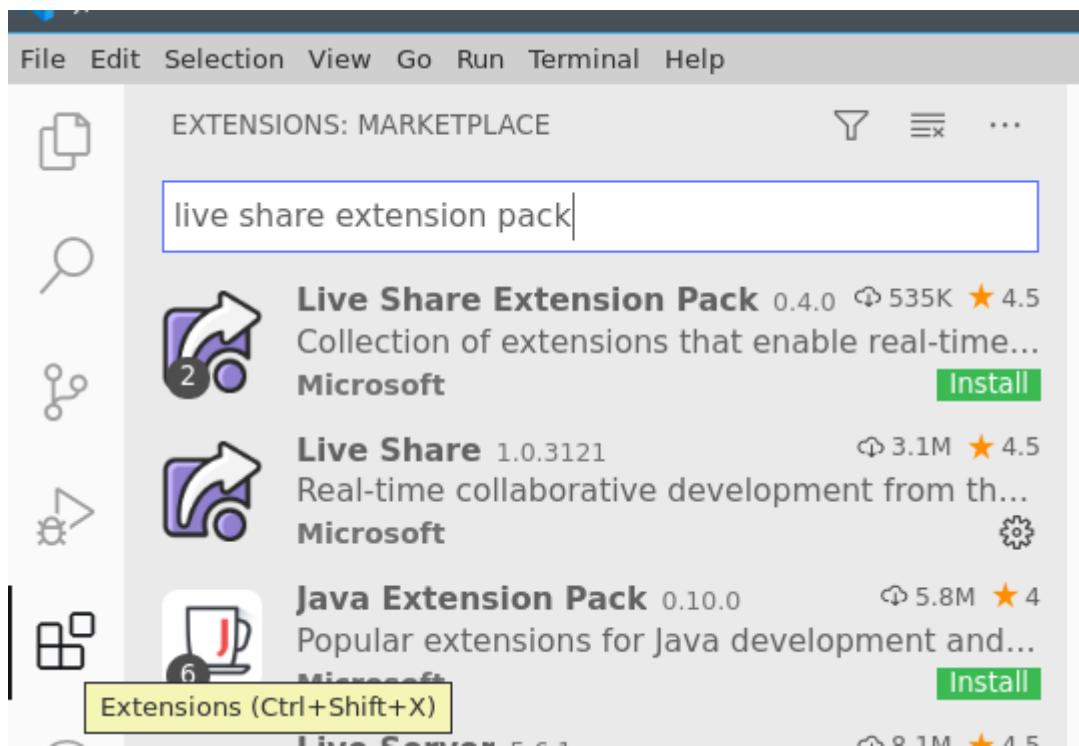

Please take some more time to familiarize with Visual Studio Code (creating files, saving files, interacting with the debugger etc.) as in the next practicals we will take this ability for granted. Once you are done you can move on and do the following exercises.

6.1.3 VS Code - collaborative coding

Visual Studio Code offers a cool way to collaborate in realtime on a project you are working on. Let's see how to set it up.

1. Install: First make sure you have [Live Share Extension Pack²⁰⁶](#) installed. It should already be included in VS Code 2019, if not go to extensions and install it.

²⁰⁶ <https://marketplace.visualstudio.com/items?itemName=MS-vsliveshare.vsliveshare-pack>

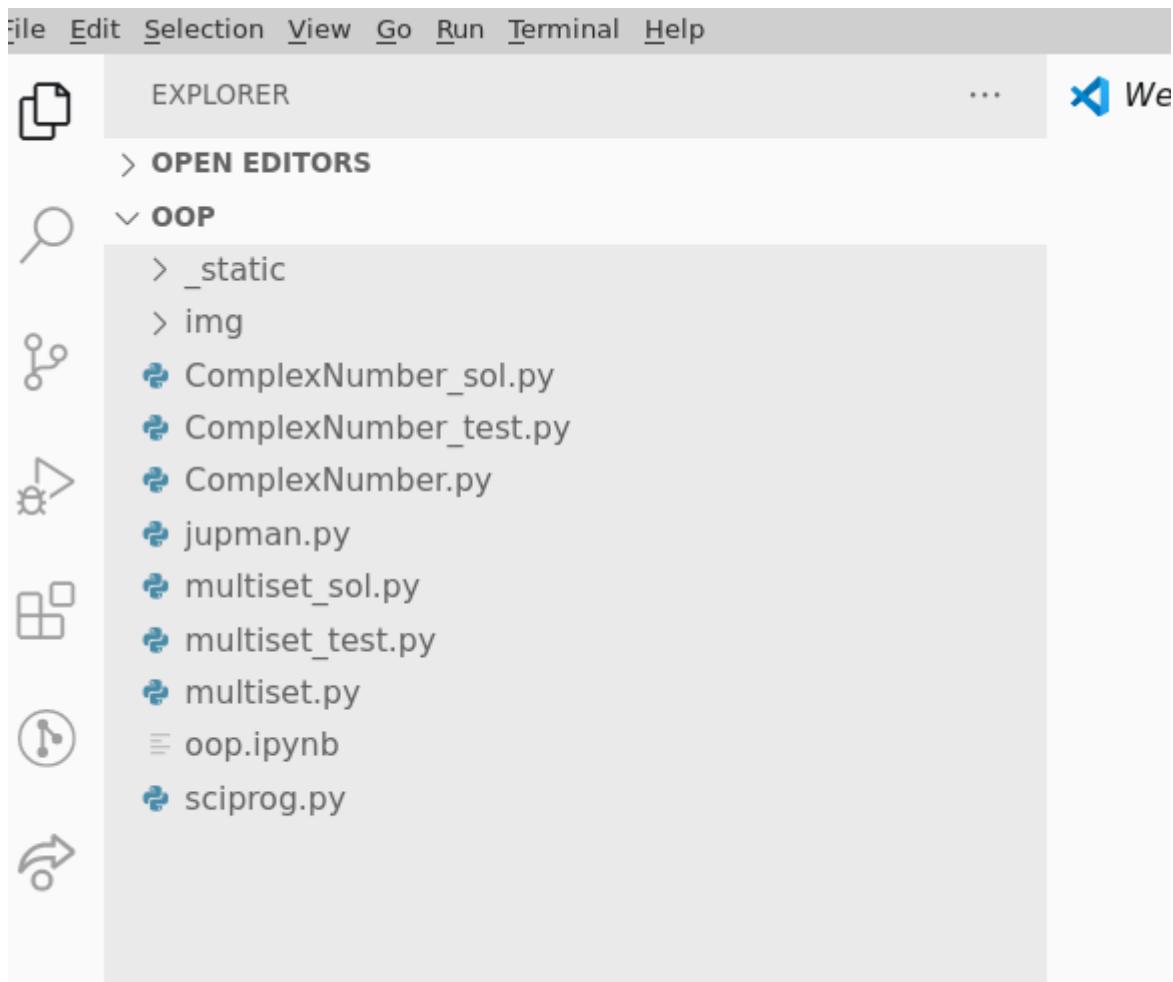

Let's share some code - as example, we will use a project taken from *Object Oriented Programming* chapter.

2. open a folder: Once you downloaded the code, open the folder where you put it with `File->Open Folder` (avoid `Open Workspace` for simplicity reasons). You should end up with something like this:

CAREFUL ABOUT WHAT YOU SHARE !!!

Once you start sharing, anything in that folder will be accessible and writable by others, we do not want to see your embarrassing desktop/home folder !

3. Sign in Now you need to sign in, for this we refer to the [the official How To²⁰⁷](#)

NOTE: in order to share your folder, you will need a [Github account²⁰⁸](#), so please if you don't have it already create one now

4. Share the folder: See [the official How To²⁰⁹](#)

6.1.4 VS Code - Sharing test runs

In Part B we will also heavily use unit tests (see [Unittest tutorial²¹⁰](#)), so it's a good idea to enabling sharing of test runs by installing [Test Explorer Live Share²¹¹](#) extension:

IT MAY NOT WORK!

It's often troublesome enough having working tests on your own system, so I expect sharing to be even more problematic. As of Nov 2020, I've never tried this thing before, so let's make a try and if it doesn't work let's just use good old screen sharing.

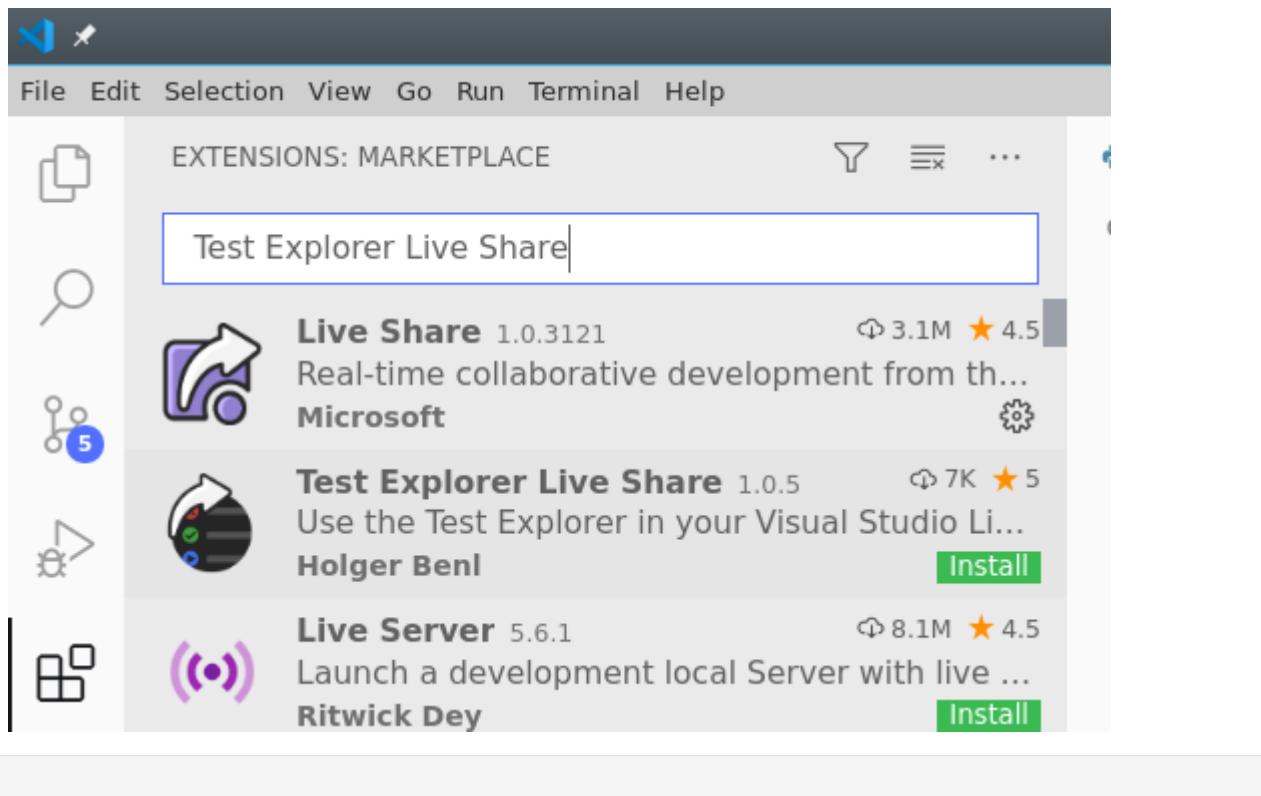

²⁰⁷ <https://docs.microsoft.com/en-us/visualstudio/liveshare/use/vscode#sign-in>

²⁰⁸ <https://github.com>

6.9 Functions - solutions

6.9.1 Download exercises zip

Browse files online²¹³

6.9.2 Introduction

References:

A function takes some parameters and uses them to produce or report some result.

In this notebook we will see how to define functions to reuse code, and talk about the scope of variables

References

- Andrea Passerini slides A04²¹⁴
- Thinking in Python, Chapter 3, Functions²¹⁵
- Thinking in Python, Chapter 6, Fruitful functions²¹⁶ **NOTE:** in the book they use the weird term 'fruitful functions' for those functions which RETURN a value (mind you, RETURN a value, which is different from PRINTing it), and use also the term 'void functions' for functions which do not return anything but have some effect like PRINTing to screen. Please ignore these terms.

What to do

- unzip exercises in a folder, you should get something like this:

```
-jupman.py
-exercises
  |- functions
    |- functions.ipynb
    |- functions-sol.ipynb
```

²¹³ <https://github.com/DavidLeoni/sciprog-ds/tree/master/functions>

²¹⁴ <http://disi.unitn.it/~passerini/teaching/2019-2020/sci-pro/slides/A04-functions.pdf>

²¹⁵ <http://greenteapress.com/thinkpython2/html/thinkpython2004.html>

²¹⁶ <http://greenteapress.com/thinkpython2/html/thinkpython2007.html>

WARNING: to correctly visualize the notebook, it MUST be in an unzipped folder !

- open Jupyter Notebook from that folder. Two things should open, first a console and then browser. The browser should show a file list: navigate the list and open the notebook `functions/functions.ipynb`
- Go on reading that notebook, and follow instructions inside.

Shortcut keys:

- to execute Python code inside a Jupyter cell, press Control + Enter
- to execute Python code inside a Jupyter cell AND select next cell, press Shift + Enter
- to execute Python code inside a Jupyter cell AND create a new cell afterwards, press Alt + Enter
- If the notebooks look stuck, try to select Kernel -> Restart

What is a function ?

A function is a block of code that has a name and that performs a task. A function can be thought of as a box that gets an input and returns an output.

Why should we use functions? For a lot of reasons including:

1. *Reduce code duplication:* put in functions parts of code that are needed several times in the whole program so that you don't need to repeat the same code over and over again;
2. *Decompose a complex task:* make the code easier to write and understand by splitting the whole program in several easier functions;

both things improve code readability and make your code easier to understand.

The basic definition of a function is:

```
def function_name(input) :
    #code implementing the function
    ...
    ...
    return return_value
```

Functions are defined with the `def` keyword that proceeds the *function_name* and then a list of parameters is passed in the brackets. A colon `:` is used to end the line holding the definition of the function. The code implementing the function is specified by using indentation. A function **might** or **might not** return a value. In the first case a `return` statement is used.

Example:

Define a function that implements the sum of two integer lists (note that there is no check that the two lists actually contain integers and that they have the same size).

```
[2]: def int_list_sum(la,lb):
    """implements the sum of two lists of integers having the same size
    """
    ret = []
    for i in range(len(la)):
        ret.append(la[i] + lb[i])
    return ret

La = list(range(1,10))
print("La:", La)
```

```
La: [1, 2, 3, 4, 5, 6, 7, 8, 9]
```

```
[3]: Lb = list(range(20,30))
print("Lb:", Lb)
Lb: [20, 21, 22, 23, 24, 25, 26, 27, 28, 29]
```

```
[4]: res = int_list_sum(La,Lb)
```

```
[5]: print("La+Lb:", res)
La+Lb: [21, 23, 25, 27, 29, 31, 33, 35, 37]
```

```
[6]: res = int_list_sum(La,La)
```

```
[7]: print("La+La", res)
La+La [2, 4, 6, 8, 10, 12, 14, 16, 18]
```

Note that once the function has been defined, it can be called as many times as wanted with different input parameters. Moreover, **a function does not do anything until it is actually called**. A function can return **0** (in this case the return value would be “None”), **1 or more** results. Notice also that collecting the results of a function is **not mandatory**.

Example: Let’s write a function that, given a list of elements, prints only the even-placed ones without returning anything.

```
[8]: def get_even_placed(myList):
    """returns the even placed elements of myList"""
    ret = [myList[i] for i in range(len(myList)) if i % 2 == 0]
    print(ret)
```

```
[9]: L1 = ["hi", "there", "from", "python", "!" ]
```

```
[10]: L2 = list(range(13))
```

```
[11]: print("L1:", L1)
L1: ['hi', 'there', 'from', 'python', '!']
```

```
[12]: print("L2:", L2)
L2: [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]
```

```
[13]: print("even L1:")
get_even_placed(L1)
even L1:
['hi', 'from', '!']
```

```
[14]: print("even L2:")
get_even_placed(L2)
even L2:
[0, 2, 4, 6, 8, 10, 12]
```

Note that the function above is polymorphic (i.e. it works on several data types, provided that we can iterate through them).

Example: Let’s write a function that, given a list of integers, returns the number of elements, the maximum and minimum.

```
[15]: def get_info(myList):
    """returns len of myList, min and max value (assumes elements are integers)"""
    tmp = myList[:] #copy the input list
    tmp.sort()
    return len(tmp), tmp[0], tmp[-1] #return type is a tuple

A = [7, 1, 125, 4, -1, 0]

print("Original A:", A, "\n")
Original A: [7, 1, 125, 4, -1, 0]
```

```
[16]: result = get_info(A)
```

```
[17]: print("Len:", result[0], "Min:", result[1], "Max:", result[2], "\n")
Len: 6 Min: -1 Max: 125
```

```
[18]: print("A now:", A)
```

```
A now: [7, 1, 125, 4, -1, 0]
```

```
[19]: def my_sum(myList):
    ret = 0
    for el in myList:
        ret += el # == ret = ret + el
    return ret

A = [1,2,3,4,5,6]
B = [7, 9, 4]
```

```
[20]: s = my_sum(A)
```

```
[21]: print("List A:", A)
print("Sum:", s)
List A: [1, 2, 3, 4, 5, 6]
Sum: 21
```

```
[22]: s = my_sum(B)
```

```
[23]: print("List B:", B)
print("Sum:", s)
List B: [7, 9, 4]
Sum: 20
```

Please note that the return value above is actually a tuple. Importantly enough, a function needs to be defined (i.e. its code has to be written) before it can actually be used.

```
[24]: A = [1,2,3]
my_sum(A)

def my_sum(myList):
```

(continues on next page)

(continued from previous page)

```
ret = 0
for el in myList:
    ret += el
return ret
```

6.9.3 Namespace and variable scope

Namespaces are mappings from *names* to objects, or in other words places where names are associated to objects. Namespaces can be considered as the context. According to Python's reference a **scope** is a *textual region of a Python program, where a namespace is directly accessible*, which means that Python will look into that *namespace* to find the object associated to a name. Four **namespaces** are made available by Python:

1. **Local**: the innermost that contains local names (inside a function or a class);
2. **Enclosing**: the scope of the enclosing function, it does not contain local nor global names (nested functions) ;
3. **Global**: contains the global names;
4. **Built-in**: contains all built in names (e.g. print, if, while, for,...)

When one refers to a name, Python tries to find it in the current namespace, if it is not found it continues looking in the namespace that contains it until the built-in namespace is reached. If the name is not found there either, the Python interpreter will throw a **NameError** exception, meaning it cannot find the name. The order in which namespaces are considered is: Local, Enclosing, Global and Built-in (LEGB).

Consider the following example:

```
[25]: def my_function():
    var = 1 #local variable
    print("Local:", var)
    b = "my string"
    print("Local:", b)
```

```
var = 7 #global variable
my_function()
print("Global:", var)
print(b)
```

```
Local: 1
Local: my string
Global: 7
```

```
-----
NameError                                 Traceback (most recent call last)
<ipython-input-56-7dd8330a24f0> in <module>
      8 my_function()
      9     print("Global:", var)
--> 10     print(b)

NameError: name 'b' is not defined
```

Variables defined within a function can only be seen within the function. That is why variable b is defined only within the function. Variables defined outside all functions are **global** to the whole program. The namespace of the local variable is within the function my_function, while outside it the variable will have its global value.

And the following:

```
[26]: def outer_function():
    var = 1 #outer

    def inner_function():
        var = 2 #inner
        print("Inner:", var)
        print("Inner:", B)

    inner_function()
    print("Outer:", var)

var = 3 #global
B = "This is B"
outer_function()
print("Global:", var)
print("Global:", B)
```

Inner: 2
Inner: This is B
Outer: 1
Global: 3
Global: This is B

Note in particular that the variable B is global, therefore it is accessible everywhere and also inside the inner_function. On the contrary, the value of var defined within the inner_function is accessible only in the namespace defined by it, outside it will assume different values as shown in the example.

In a nutshell, remember the three simple rules seen in the lecture. Within a **def**:

1. Name assignments create local names by default;
2. Name references search the following four scopes in the order:
local, enclosing functions (if any), then global and finally built-in (LEGB)
3. Names declared in global and nonlocal statements map assigned names to enclosing module and function scopes.

6.9.4 Argument passing

Arguments are the parameters and data we pass to functions. When passing arguments, there are three important things to bear in mind are:

1. Passing an argument is actually assigning an object to a local variable name;
2. Assigning an object to a variable name within a function **does not affect the caller**;
3. Changing a **mutable** object variable name within a function **affects the caller**

Consider the following examples:

```
[27]: """Assigning the argument does not affect the caller"""

def my_f(x):
    x = "local value" #local
    print("Local: ", x)

x = "global value" #global
my_f(x)
```

(continues on next page)

(continued from previous page)

```
print("Global:", x)
my_f(x)
```

```
Local: local value
Global: global value
Local: local value
```

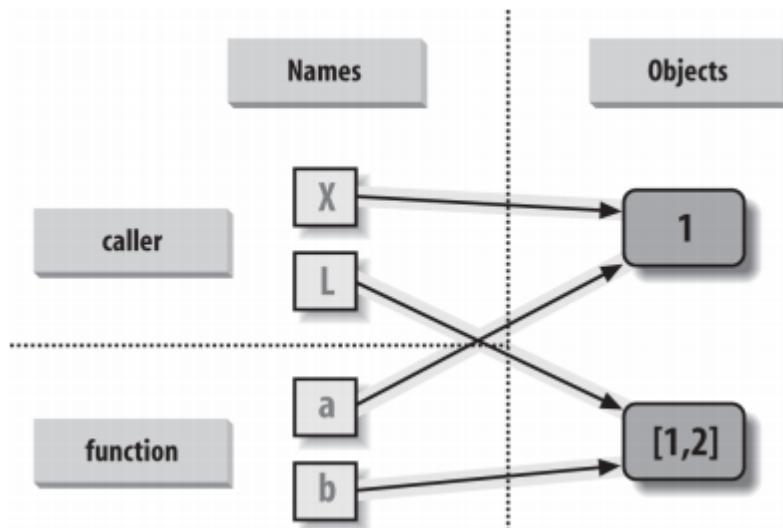

[28]: *"'"Changing a mutable affects the caller"""*

```
def my_f(myList):
    myList[1] = "new value1"
    myList[3] = "new value2"
    print("Local: ", myList)

myList = ["old value"]*4
print("Global:", myList)
my_f(myList)
print("Global now: ", myList)
```

```
Global: ['old value', 'old value', 'old value', 'old value']
Local: ['old value', 'new value1', 'old value', 'new value2']
Global now: ['old value', 'new value1', 'old value', 'new value2']
```

Recall what seen in the lecture:

The behaviour above is because **immutable objects** are passed **by value** (therefore it is like making a copy), while **mutable objects** are passed **by reference** (therefore changing them effectively changes the original object).

To avoid making changes to a **mutable object** passed as parameter one needs to **explicitely make a copy** of it.

Consider the example seen before. **Example:** Let's write a function that, given a list of integers, returns the number of elements, the maximum and minimum.

[29]:

```
def get_info(myList):
    """returns len of myList, min and max value (assumes elements are integers)"""
    myList.sort()
```

(continues on next page)

(continued from previous page)

```

return len(myList), myList[0], myList[-1] #return type is a tuple

def get_info_copy(myList):
    """returns len of myList, min and max value (assumes elements are integers)"""
    tmp = myList[:] #copy the input list!!!!
    tmp.sort()
    return len(tmp), tmp[0], tmp[-1] #return type is a tuple

A = [7, 1, 125, 4, -1, 0]
B = [70, 10, 1250, 40, -10, 0, 10]

print("A:", A)
result = get_info(A)

A: [7, 1, 125, 4, -1, 0]

```

```
[30]: print("Len:", result[0], "Min:", result[1], "Max:", result[2] )

Len: 6 Min: -1 Max: 125
```

```
[31]: print("A now:", A) #whoops A is changed!!!

A now: [-1, 0, 1, 4, 7, 125]
```

```
[32]: print("\nB:", B)

B: [70, 10, 1250, 40, -10, 0, 10]
```

```
[33]: result = get_info_copy(B)
```

```
[34]: print("Len:", result[0], "Min:", result[1], "Max:", result[2] )

Len: 7 Min: -10 Max: 1250
```

```
[35]: print("B now:", B) #B is not changed!!!

B now: [70, 10, 1250, 40, -10, 0, 10]
```

Positional arguments

Arguments can be passed to functions following the order in which they appear in the function definition.

Consider the following example:

```
[36]: def print_parameters(a,b,c,d):
    print("1st param:", a)
    print("2nd param:", b)
    print("3rd param:", c)
    print("4th param:", d)

print_parameters("A", "B", "C", "D")

1st param: A
2nd param: B
```

(continues on next page)

(continued from previous page)

```
3rd param: C  
4th param: D
```

Passing arguments by keyword

Given the name of an argument as specified in the definition of the function, parameters can be passed using the **name = value** syntax.

For example:

```
[37]: def print_parameters(a,b,c,d):  
    print("1st param:", a)  
    print("2nd param:", b)  
    print("3rd param:", c)  
    print("4th param:", d)  
  
print_parameters(a = 1, c=3, d=4, b=2)  
  
1st param: 1  
2nd param: 2  
3rd param: 3  
4th param: 4
```

```
[38]: print_parameters("first","second",d="fourth",c="third")  
  
1st param: first  
2nd param: second  
3rd param: third  
4th param: fourth
```

Arguments passed positionally and by name can be used at the same time, but parameters passed by name must always be to the left of those passed by name. The following code in fact is not accepted by the Python interpreter:

```
def print_parameters(a,b,c,d):  
    print("1st param:", a)  
    print("2nd param:", b)  
    print("3rd param:", c)  
    print("4th param:", d)  
  
print_parameters(d="fourth",c="third", "first","second")
```

```
File "<ipython-input-60-4991b2c31842>", line 7  
    print_parameters(d="fourth",c="third", "first","second")  
                                         ^  
SyntaxError: positional argument follows keyword argument
```

Specifying default values

During the definition of a function it is possible to specify default values. The syntax is the following:

```
def my_function(par1 = val1, par2 = val2, par3 = val3):
```

Consider the following example:

```
[39]: def print_parameters(a="defaultA", b="defaultB",c="defaultC"):
    print("a:",a)
    print("b:",b)
    print("c:",c)
```

```
print_parameters("param_A")
```

```
a: param_A
b: defaultB
c: defaultC
```

```
[40]: print_parameters(b="PARAMETER_B")
```

```
a: defaultA
b: PARAMETER_B
c: defaultC
```

```
[41]: print_parameters()
```

```
a: defaultA
b: defaultB
c: defaultC
```

```
[42]: print_parameters(c="PARAMETER_C", b="PAR_B")
```

```
a: defaultA
b: PAR_B
c: PARAMETER_C
```

6.9.5 Simple exercises

sum2

⊕ Write function sum2 which given two numbers x and y RETURN their sum

QUESTION: Why do we call it `sum2` instead of just `sum` ??

```
[43]: sum([2, 51])
```

```
[43]: 53
```

```
<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"
data-jupman-show="Show answer"
data-jupman-hide="Hide">Show answer</a><div class="jupman-sol jupman-sol-question" style="display:none">
```

ANSWER: `sum` is already defined as standard python function, we do not want to overwrite it. Look at how in the following snippet it displays in green:

```
>>> sum([5, 8])
```

```
13
```

```
</div>

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"
  data-jupman-show="Show solution"
  data-jupman-hide="Hide">Show solution</a><div class="jupman-sol jupman-sol-code" style="display:none">

[44]: # write here

def sum2(x,y):
    return x + y

</div>

[44]: # write here

[45]: s = sum2(3,6)
print(s)

9

[46]: s = sum2(-1,3)
print(s)

2
```

comparep

⊕ Write a function comparep which given two numbers x and y, PRINTS x is greater than y, x is less than y, x is equal to y

NOTE: in print, put real numbers. For example, comparep(10,5) should print:

```
10 is greater than 5
```

HINT: to print numbers and text, use commas in print:

```
print(x, " is greater than ")
```

```
<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"
  data-jupman-show="Show solution"
  data-jupman-hide="Hide">Show solution</a><div class="jupman-sol jupman-sol-code" style="display:none">
```

```
[47]: # write here
def comparep(x,y):
    if x > y:
        print(x, " is greater than ", y)
    elif x < y:
        print(x, " is less than ", y)
    else:
        print(x, " is equal to ", y)

</div>
```

```
[47]: # write here
```

```
[48]: comparep(10,5)
10  is greater than 5
```

```
[49]: comparep(3,8)
3  is less than 8
```

```
[50]: comparep(3,3)
3  is equal to 3
```

comparer

⊕ Write function `comparer` which given two numbers `x` and `y` RETURN the STRING '`>`' if `x` is greater than `y`, the STRING '`<`' if `x` is less than `y` or the STRING '`==`' if `x` is equal to `y`

[Show solution](#)

</div>

```
[51]: # write here
def comparer(x,y):
    if x > y:
        return '>'
    elif x < y:
        return '<'
    else:
        return '=='
```

</div>

```
[51]: # write here
```

```
[52]: c = comparer(10,5)
print(c)
>
```

```
[53]: c = comparer(3,7)
print(c)
<
```

```
[54]: c = comparer(3,3)
print(c)
==
```

even

⊕ Write a function even which given a number x, RETURN True if x is even, otherwise RETURN False

HINT: a number is even when the rest of division by two is zero. To obtaining the remainder of division, write $x \% 2$

```
[55]: # Example:  
2 % 2
```

```
[55]: 0
```

```
[56]: 3 % 2
```

```
[56]: 1
```

```
[57]: 4 % 2
```

```
[57]: 0
```

```
[58]: 5 % 2
```

```
[58]: 1
```

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"
data-jupman-show="Show solution"
data-jupman-hide="Hide">Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[59]: # write here  
def even(x):  
    return x % 2 == 0
```

</div>

```
[59]: # write here
```

```
[60]: p = even(2)  
print(p)  
True
```

```
[61]: p = even(3)  
print(p)  
False
```

```
[62]: p = even(4)  
print(p)  
True
```

```
[63]: p = even(5)  
print(p)  
False
```

```
[64]: p = even(0)  
print(p)
```

```
True
```

gre

⊕ Write a function `gre` that given two numbers `x` and `y`, RETURN the greatest number.

If they are equal, RETURN any number.

<a class="jupman-sol jupman-sol-toggler" onclick="jupman.toggleSolution(this);"

```
[65]: # write here
```

```
def gre(x,y):
    if x > y:
        return x
    else:
        return y
```

</div>

```
[65]: # write here
```

```
[66]: m = gre(3,5)
print(m)
```

5

```
[67]: m = gre(6,2)
print(m)
```

6

```
[68]: m = gre(4,4)
print(m)
```

4

```
[69]: m = gre(-5,2)
print(m)
```

2

```
[70]: m = gre(-5, -3)
print(m)
```

-3

is_vocal

⊕ Write a function `is_vocal` in which a character `char` is passed as parameter, and PRINTS 'yes' if the character is a vocal, otherwise PRINTS 'no' (using the `print`s).

```
>>> is_vocal("a")
'yes'

>>> is_vocal("c")
'no'
```

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[71]: # write here

def is_vocal(char):
    if char == 'a' or char == 'e' or char == 'i' or char == 'o' or char == 'u':
        print('yes')
    else:
        print('no')

</div>
```

```
[71]: # write here
```

sphere_volume

⊕ The volume of a sphere of radius r is $4/3r^3$

Write a function `sphere_volume(radius)` which given a `radius` of a sphere, PRINTS the volume.

NOTE: assume $\pi = 3.14$

```
>>> sphere_volume(4)
267.94666666666666
```

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[72]: # write here

def sphere_volume(radius):
    print((4/3)*3.14*(radius**3))

</div>
```

```
[72]: # write here
```

ciri

⊕ Write a function `ciri(name)` which takes as parameter the string name and RETURN True if it is equal to the name 'Cirillo'

```
>>> r = ciri("Cirillo")
>>> r
True

>>> r = ciri("Cirillo")
>>> r
False
```

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

[73]: # write here

```
def ciri(name):
    if name == "Cirillo":
        return True
    else:
        return False
```

</div>

[73]: # write here

age

⊕ Write a function `age` which takes as parameter year of birth and RETURN the age of the person

**Suppose the current year is known, so to represent it in the function body use a constant like 2019:

```
>>> a = age(2003)
>>> print(a)
16
```

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

[74]: # write here

```
def age(year):
    return 2019 - year
```

</div>

[74]: # write here

6.9.6 Verify comprehension

Following exercises require you to know:

ATTENTION

Following exercises require you to know:

Complex statements: Andrea Passerini slides A03²¹⁷

Tests with asserts²¹⁸: Following exercises contain automated tests to help you spot errors. To understand how to do them, read before Error handling and testing²¹⁹

gre3

⊕⊕ Write a function `gre3(a,b,c)` which takes three numbers and RETURN the greatest among them

Examples:

```
>>> gre3(1,2,4)
4

>>> gre3(5,7,3)
7

>>> gre3(4,4,4)
4
```

[75]: # write ehre

```
def gre3(a,b,c):
    if a > b:
        if a>c:
            return a
        else:
            return c
    else:
        if b > c:
            return b
        else:
            return c

assert gre3(1,2,4) == 4
assert gre3(5,7,3) == 7
assert gre3(4,4,4) == 4
```

²¹⁹ <https://sciprog.davidleoni.it/errors-and-testing/errors-and-testing-sol.html>

final_price

⊕⊕ The cover price of a book is € 24,95, but a library obtains 40% of discount. Shipping costs are € 3 for first copy and 75 cents for each additional copy. How much n copies cost ?

Write a function `final_price(n)` which RETURN the price.

ATTENTION 1: For numbers Python wants a dot, NOT the comma !

ATTENTION 2: If you ordered zero books, how much should you pay ?

HINT: the 40% of 24,95 can be calculated by multiplying the price by 0.40

```
>>> p = final_price(10)
>>> print(p)

159.45

>>> p = final_price(0)
>>> print(p)

0
```

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[76]: def final_price(n):

    if n == 0:
        return 0
    else:
        return n* 24.95*0.6 + 3 + (n-1)*0.75

assert final_price(10) == 159.45
assert final_price(0) == 0
```

</div>

```
[76]: def final_price(n):
    raise Exception('TODO IMPLEMENT ME !')

assert final_price(10) == 159.45
assert final_price(0) == 0
```

arrival_time

⊕⊕⊕ By running slowly you take 8 minutes and 15 seconds per mile, and by running with moderate rhythm you take 7 minutes and 12 seconds per mile.

Write a function `arrival_time(n,m)` which, supposing you start at 6:52, given n miles run with slow rhythm and m with moderate rhythm, PRINTs arrival time.

- **HINT 1:** to calculate an integer division, use `/`
- **HINT 2:** to calculate the remainder of integer division, use the module operator `%`

```
>>> arrival_time(2,2)
7:22
```

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[77]: def arrival_time(n,m):  
  
    starting_hours = 6  
    starting_minutes = 52  
  
    # passed seconds  
    seconds = n * 495 + m * 432  
  
    # passed time  
    seconds_two = seconds % 60  
    minutes = seconds // 60  
    hours = minutes // 60  
  
    arrival_hours= hours + starting_hours  
    arrival_minutes= minutes + starting_minutes  
  
    final_minutes = arrival_minutes % 60  
    final_hours = arrival_minutes // 60 + arrival_hours  
  
    return str(final_hours) + ":" + str(final_minutes)  
  
assert arrival_time(0,0) == '6:52'  
assert arrival_time(2,2) == '7:22'  
assert arrival_time(2,5) == '7:44'  
assert arrival_time(8,5) == '9:34'
```

</div>

```
[77]: def arrival_time(n,m):  
    raise Exception('TODO IMPLEMENT ME !')  
  
assert arrival_time(0,0) == '6:52'  
assert arrival_time(2,2) == '7:22'  
assert arrival_time(2,5) == '7:44'  
assert arrival_time(8,5) == '9:34'
```

[]:

6.9.7 Lambda functions

Lambda functions are functions which:

- have no name
- are defined on one line, typically right where they are needed
- their body is an expression, thus you need no `return`

Let's create a lambda function which takes a number `x` and doubles it:

```
[78]: lambda x: x*2
```

```
[78]: <function __main__.<lambda>(x)>
```

As you see, Python created a function object, which gets displayed by Jupyter. Unfortunately, at this point the function object got lost, because that is what happens to any object created by an expression that is not assigned to a variable.

To be able to call the function, we will thus convenient to assign such function object to a variable, say `f`:

```
[79]: f = lambda x: x*2
```

```
[80]: f
```

```
[80]: <function __main__.<lambda>(x)>
```

Great, now we have a function we can call as many times as we want:

```
[81]: f(5)
```

```
[81]: 10
```

```
[82]: f(7)
```

```
[82]: 14
```

So writing

```
[83]: def f(x):
    return x*2
```

or

```
[84]: f = lambda x: x*2
```

are completely equivalent forms, the main difference being with `def` we can write functions with bodies on multiple lines. Lambdas may appear limited, so why should we use them? Sometimes they allow for very concise code. For example, imagine you have a list of tuples holding animals and their lifespan:

```
[85]: animals = [('dog', 12), ('cat', 14), ('pelican', 30), ('eagle', 25), ('squirrel', 6)]
```

If you want to sort them, you can try the `.sort` method but it will not work:

```
[86]: animals.sort()
```

```
[87]: animals
```

```
[87]: [('cat', 14), ('dog', 12), ('eagle', 25), ('pelican', 30), ('squirrel', 6)]
```

Clearly, this is not what we wanted. To get proper ordering, we need to tell python that when it considers a tuple for comparison, it should extract the lifespan number. To do so, Pyhton provides us with `key` parameter, which we must pass a function that takes as argument the list element under consideration (in this case a tuple) and will return a trasformation of it (in this case the number at 1-th position):

```
[88]: animals.sort(key=lambda t: t[1])
```

```
[89]: animals
```

```
[89]: [('squirrel', 6), ('dog', 12), ('cat', 14), ('eagle', 25), ('pelican', 30)]
```

Now we got the ordering we wanted. We could have written the thing as

```
[90]: def myf(t):
        return t[1]

animals.sort(key=myf)
animals
[90]: [('squirrel', 6), ('dog', 12), ('cat', 14), ('eagle', 25), ('pelican', 30)]
```

but lambdas clearly save some keyboard typing

Notice lambdas can take multiple parameters:

```
[91]: mymul = lambda x,y: x * y
mymul(2,5)
[91]: 10
```

Exercises: lambdas

apply_borders

⊕ Write a function `apply_borders` which takes a function `f` as parameter and a sequence, and RETURN a tuple holding two elements:

- first element is obtained by applying `f` to the first element of the sequence
- second element is obtained by applying `f` to the last element of the sequence

Example:

```
>>> apply_borders(lambda x: x.upper(), ['the', 'river', 'is', 'very', 'long'])
('THE', 'LONG')
>>> apply_borders(lambda x: x[0], ['the', 'river', 'is', 'very', 'long'])
('t', 'l')
```

Show solution<div class="jupman-sol" jupman-sol-code" style="display:none">

```
[92]: # write here

def apply_borders(f, seq):
    return ( f(seq[0]),    f(seq[-1]) )
```

</div>

```
[92]: # write here
```

```
[93]: print(apply_borders(lambda x: x.upper(), ['the', 'river', 'is', 'very', 'long']))
print(apply_borders(lambda x: x[0], ['the', 'river', 'is', 'very', 'long']))

('THE', 'LONG')
('t', 'l')
```

process

⊗⊗ Write a lambda expression to be passed as first parameter of the function process defined down here, so that a call to process generates a list as shown here:

```
>>> f = PUT_YOUR_LAMBDA_FUNCTION
>>> process(f, ['d', 'b', 'a', 'c', 'e', 'f'], ['q', 's', 'p', 't', 'r', 'n'])
['An', 'Bp', 'Cq', 'Dr', 'Es', 'Ft']
```

NOTE: process is already defined, you do not need to change it

Show solution<div class="jupman-sol jupman-sol-code" style="display:none">

```
[94]: def process(f, lista, listb):
    ordA = list(sorted(lista))
    ordB = list(sorted(listb))
    ret = []
    for i in range(len(lista)):
        ret.append(f(ordA[i], ordB[i]))
    return ret

# write here the f = lambda ...
f = lambda x,y: x.upper() + y
```

</div>

```
[94]: def process(f, lista, listb):
    ordA = list(sorted(lista))
    ordB = list(sorted(listb))
    ret = []
    for i in range(len(lista)):
        ret.append(f(ordA[i], ordB[i]))
    return ret

# write here the f = lambda ...
```

```
[95]: process(f, ['d', 'b', 'a', 'c', 'e', 'f'], ['q', 's', 'p', 't', 'r', 'n'])
[95]: ['An', 'Bp', 'Cq', 'Dr', 'Es', 'Ft']
```

6.10 Error handling and testing solutions

- **Error handling was** moved to softpython²²⁰

According to the part of the course you are following, we will review two kinds of tests:

- **Part A testing with asserts:** moved to SoftPython²²¹
- **Part B testing with unittest:** read this notebook

²²⁰ <https://en.softpython.org/errors-and-testing/errors-and-testing-sol.html>

²²¹ <https://en.softpython.org/errors-and-testing/errors-and-testing-sol.html#Testing-with-asserts>

6.10.1 Testing with Unittest

NOTE: Testing with Unittest is only done in PART B of this course

Is there anything better than `assert` for testing? `assert` can be a quick way to check but doesn't tell us exactly which is the wrong number in the list returned by `even_numbers(5)`. Luckily, Python offers us a better option, which is a complete testing framework called `unittest`²²². We will use `unittest` because it is the standard one, but if you're doing other projects you might consider using better ones like `pytest`²²³ (note it can also execute tests made with `unittest`, so if your visualstudio code for some reason doesn't work with `unittest`, you can try setting `pytest` as test framework)

So let's give `unittest` a try. Suppose you have a file called `file_test.py` like this:

```
[2]: import unittest

def even_numbers(n):
    """
    Return a list of the first n even numbers

    Zero is considered to be the first even number.

    >>> even_numbers(5)
    [0, 2, 4, 6, 8]
    """
    r = [2 * x for x in range(n)]
    r[n // 2] = 3    # <-- evil bug, puts number '3' in the middle
    return r

class MyTest(unittest.TestCase):

    def test_long_list(self):
        self.assertEqual(even_numbers(5), [0, 2, 4, 6, 8])
```

We won't explain what `class` mean (for classes see the book chapter²²⁴), the important thing to notice is the method definition:

```
def test_long_list(self):
    self.assertEqual(even_numbers(5), [0, 2, 4, 6, 8])
```

In particular:

- method is declared like a function, and begins with '`test_`' word
- method takes `self` as parameter
- `self.assertEqual(even_numbers(5), [0, 2, 4, 6, 8])` executes the assertion. Other assertions could be `self.assertTrue(some_condition)` or `self.assertFalse(some_condition)`

²²² <https://docs.python.org/3/library/unittest.html>

²²³ <https://docs.pytest.org/>

²²⁴ <http://interactivepython.org/runestone/static/pythonds/Introduction/ObjectOrientedProgramminginPythonDefiningClasses.html>

Running tests

To run the tests, enter the following command in the terminal:

```
python -m unittest file_test
```

!!!! WARNING: In the call above, DON'T append the extension .py to file_test !!!!!

!!!! WARNING: Still, on the hard-disk the file MUST be named with a .py at the end, like file_test.py!!!!

You should see an output like the following:

```
[3]: jupman.show_run(MyTest)

F
=====
FAIL: test_long_list (__main__.MyTest)
-----
Traceback (most recent call last):
  File "<ipython-input-2-ec89a972a892>", line 19, in test_long_list
    self.assertEqual(even_numbers(5), [0,2,4,6,8])
AssertionError: Lists differ: [0, 2, 3, 6, 8] != [0, 2, 4, 6, 8]

First differing element 2:
3
4

- [0, 2, 3, 6, 8]
?
^

+ [0, 2, 4, 6, 8]
?
^

-----
Ran 1 test in 0.001s

FAILED (failures=1)
```

Now you can see a nice display of where the error is, exactly in the middle of the list!

When tests don't run

When `-m unittest` does not work and you keep seeing absurd errors like Python not finding a module and you are getting desperate (especially because Python has `unittest` included by *default*, there is no need to install it!), try putting the following code at the very end of the file you are editing:

```
unittest.main()
```

Then simply run your file with:

```
python file_test.py
```

In this case it should REALLY work. If it still doesn't, call the Ghostbusters. Or, better, the IndentationBusters, you're likely having tabs mixed with spaces mixed with very bad luck.

Adding tests

How can we add (good) tests? Since best ones are usually short, it would be better starting small boundary cases. For example like `n=1` , which according to function documentation should produce a list containing zero:

```
[9]: class MyTest(unittest.TestCase):

    def test_one_element(self):
        self.assertEqual(even_numbers(1), [0])

    def test_long_list(self):
        self.assertEqual(even_numbers(5), [0, 2, 4, 6, 8])
```

Let's call again the command:

```
python -m unittest file_test
```

```
[5]: jupman.show_run(MyTest)

FF
=====
FAIL: test_long_list (___main___.MyTest)
-----
Traceback (most recent call last):
  File "<ipython-input-4-306d9f1c7777>", line 7, in test_long_list
    self.assertEqual(even_numbers(5),[0,2,4,6,8])
AssertionError: Lists differ: [0, 2, 3, 6, 8] != [0, 2, 4, 6, 8]

First differing element 2:
3
4

- [0, 2, 3, 6, 8]
?
^

+ [0, 2, 4, 6, 8]
?
^

=====
FAIL: test_one_element (___main___.MyTest)
-----
Traceback (most recent call last):
  File "<ipython-input-4-306d9f1c7777>", line 4, in test_one_element
    self.assertEqual(even_numbers(1),[0])
AssertionError: Lists differ: [3] != [0]

First differing element 0:
3
0

- [3]
+
[0]

-----
Ran 2 tests in 0.003s

FAILED (failures=2)
```

From the tests we can now see there is clearly something wrong with the number 3 that keeps popping up, making both tests fail. You can see immediately which tests have failed by looking at the first two FF at the top of the output. Let's fix the code by removing the buggy line:

```
[10]: def even_numbers(n):
    """
    Return a list of the first n even numbers

    Zero is considered to be the first even number.

    >>> even_numbers(5)
    [0, 2, 4, 6, 8]
    """
    r = [2 * x for x in range(n)]
    # NOW WE COMMENTED THE BUGGY LINE  r[n // 2] = 3  # <- evil bug, puts number '3
    ↵ ' in the middle
    return r
```

And call yet again the command:

```
python -m unittest file_test
```

```
[7]: jupman.show_run(MyTest)
..
-----
Ran 2 tests in 0.002s
OK
```

Wonderful, all the two tests have passed and we got rid of the bug.

WARNING: DON'T DUPLICATE TEST CLASS NAMES AND/OR METHODS!

In the following, you will be asked to add tests. Just add **NEW** methods with **NEW** names to the **EXISTING** class **MyTest** !

Exercise: boundary cases

Think about other boundary cases, and try to add corresponding tests.

- Can we ever have an empty list?
- Can n be equal to zero? Add a test **inside MyTest class** for its expected result.
- Can n be negative? In this case the function text tells us nothing about the expected behaviour, so we might choose it now: either the function raises an error, or it gives a back something, like i.e. list of even negative numbers. Try to modify `even_numbers` and add a relative test **inside MyTest class** for expecting even negative numbers (starting from zero).

Exercise: expecting assertions

What if user passes us a float like 3.5 instead of an integer? If you try to run `even_numbers(3.5)` you will discover it works anyway, but we might decide to be picky and not accept inputs other than integers. Try to modify `even_numbers` to make so that when input is not of type `int`, raises `TypeError`²²⁵ (to check for type, you can write `type(n) == int`).

To test for it, add following test **inside MyTest class**:

```
def test_type(self):  
  
    with self.assertRaises(TypeError):  
        even_numbers(3.5)
```

The `with` block tells Python to expect the code inside the `with` block to raise the exception `TypeError`²²⁶:

- If `even_numbers(3.5)` actually raises `TypeError` exception, nothing happens
- If `even_numbers(3.5)` does not raise `TypeError` exception, `with` raises `AssertionError`

After you completed previous task, consider when the input is the float 4.0: in this case it might make sense to still accept it, so modify `even_numbers` accordingly and write a test for it.

Exercise: good tests

What difference is there between the following two test classes? Which one is better for testing?

```
class MyTest(unittest.TestCase):  
  
    def test_one_element(self):  
        self.assertEqual(even_numbers(1), [0])  
  
    def test_long_list(self):  
        self.assertEqual(even_numbers(5), [0, 2, 4, 6, 8])
```

and

```
class MyTest(unittest.TestCase):  
  
    def test_stuff(self):  
        self.assertEqual(even_numbers(1), [0])  
        self.assertEqual(even_numbers(5), [0, 2, 4, 6, 8])
```

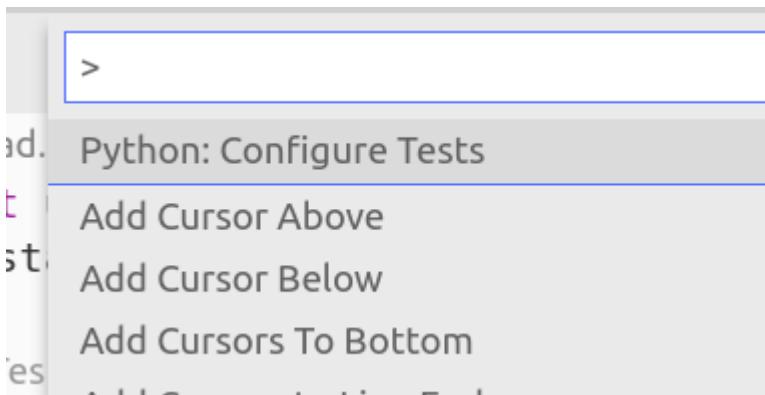

Running unittests in Visual Studio Code

You can run and debug tests in Visual Studio Code, which is very handy. First, you need to set it up.

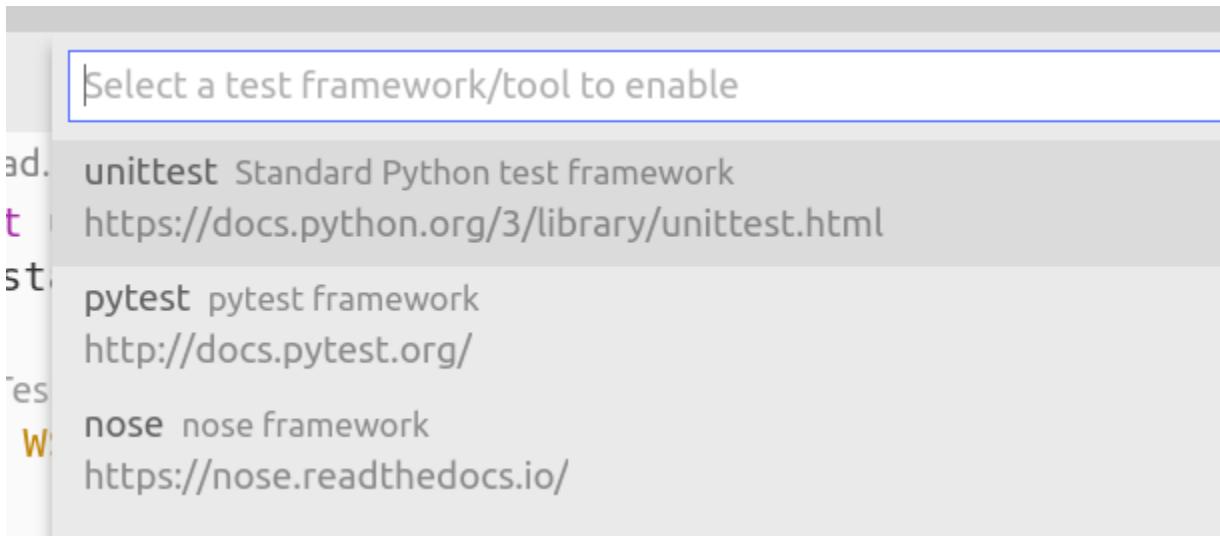

1. Hit Control-Shift-P (on Mac: Command-Shift-P) and type Python: Configure Tests

²²⁵ <https://docs.python.org/3/library/exceptions.html#TypeError>

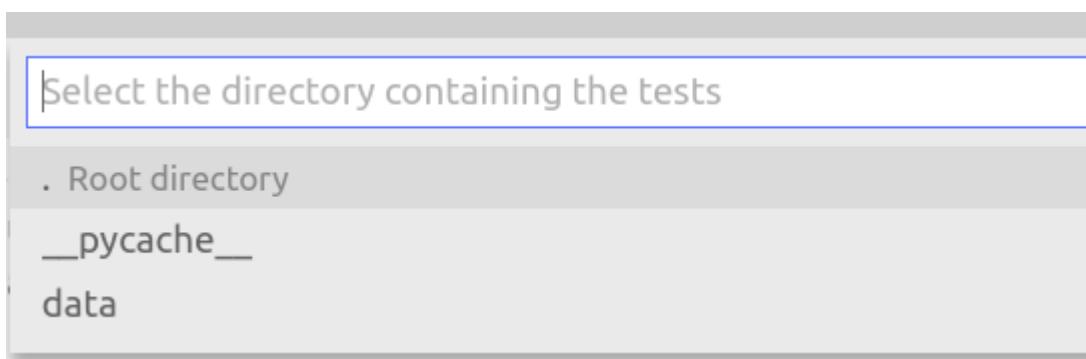

²²⁶ <https://docs.python.org/3/library/exceptions.html#TypeError>

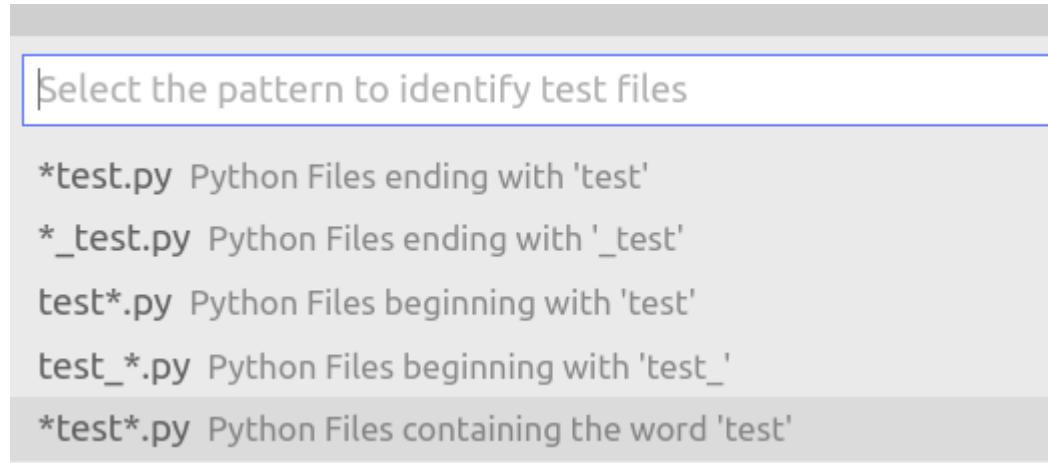

2. Select unittest:

3. Select . root directory (we assume tests are in the folder that you've opened):

4. Select *test*.py Python files containing the word 'test':

Hopefully, on the currently opened test file new labels should appear above class and test methods, like in the following example. Try to click on them:

The screenshot shows a code editor window with two tabs: "stack_test.py" and "stack2_test.py". The "stack2_test.py" tab is active, displaying the following Python code:

```
1 import unittest
2 from stack_solution import *
3
4 class WStackTest(unittest.TestCase):
5
6     def test_01_init(self):
7         s = WStack()
8
9     def test_02_weight(self):
10        s = WStack()
11        self.assertEqual(s.weight(), 1)
```

Labels are present above the class definition and each test method:

- For the class definition: "WStackTest" has a "Run Test" and "Debug Test" label.
- For the first test method: "test_01_init" has a "Run Test" and "Debug Test" label.
- For the second test method: "test_02_weight" has a "Run Test" and "Debug Test" label.

In the bottom bar, you should see a recap of tests run (right side of the picture):

TROUBLESHOOTING

If you encounter problems running tests and have Anaconda, sometimes an easy solution can be just closing Visual Studio Code and running it from the Anaconda Navigator. You can also try updating it.

Running tests by console does not work:

- remember to SAVE the files before executing tests: in Windows, a file appears as not saved when its filename in the tab is written in italics; on Linux, you might see a dot to the right of the filename

Run Test label does not show up in code:

- if you see red squiggles in the code, most probably syntax is not correct and thus no test will get discovered ! If this is the case, fix the syntax error, SAVE, and then tell Visual Studio to discover test.
- you might also try *Right click->Run current Test File*.
- try *Selecting another testing framework*, try pytest, which is also capable to discover and execute unittests.
- if you are really out of luck with the editor, there is always the option of running tests from the console.

Spend time using the console !!!

During exams VSCode testing might not work, so please be prepared to use the console

6.10.2 Functional programming

In functional programming, functions behave as mathematical ones so they always take some parameter and return new data without ever changing the input. They say functional programming is easier to test. Why?

Immutable data structures: all data structures are (or are meant to be) immutable -> no code can ever tweak your data, so other developers just cannot (should not) be able to inadvertently change your data.

Simpler parallel computing: point above is particularly important in parallel computation, when the system can schedule thread executions differently *each* time you run the program: this implies that when you have multiple threads it can be very very hard to reproduce a bug where a thread wrongly changes a data which is supposed to be exclusively managed by another one: it might fail in one run and succeed in another just because the system scheduled differently the code execution! Functional programming frameworks like [Spark²²⁷](#) solve these problems very nicely.

Easier to reason about code: it is much easier to reason about functions, as we can use standard equational reasoning on input/outputs as traditionally done in algebra. To understand what we're talking about, you can see these slides: [Visual functional programming²²⁸](#) (will talk more about it in class)

7.1 OOP

7.1.1 Download exercises zip

Browse files online²³⁰

7.1.2 What to do

- unzip exercises in a folder, you should get something like this:

```
oop
ComplexNumber.py
ComplexNumber_test.py
ComplexNumber_sol.py
multiset.py
multiset_test.py
multiset_sol.py
matrix.py
oop.ipynb
jupman.py
sciprog.py
```

This time you will not write in the notebook, instead you will edit .py files in Visual Studio Code.

Now proceed reading.

7.1.3 1. Abstract Data Types (ADT) Theory

1.1. Intro

- Theory from the slides:
 - Andrea Passerini - Programming paradigms, Object-Oriented Python²³¹
- Object Oriented programming on the the book²³² (In particular, Fraction class²³³, in this course we won't focus on inheritance)

²³⁰ <https://github.com/DavidLeoni/sciprog-ds/tree/master/oop>

²³³ <https://runestone.academy/runestone/books/published/pythonds/Introduction/ObjectOrientedProgramminginPythonDefiningClasses.html#a-fraction-class>

1.2. Complex number theory

A **complex number** is a **number** that can be expressed in the form $a + bi$, where a and b are **real numbers** and i is the **imaginary unit** which satisfies the equation $i^2 = -1$. In this expression, a is the **real part** and b is the **imaginary part** of the **complex number**.

Complex number - Wikipedia
https://en.wikipedia.org/wiki/Complex_number

1.3. Datatypes the old way

From the definition we see that to identify a complex number **we need two float values**. One number is for the ***real* part**, and another number is for the ***imaginary* part**.

How can we represent this in Python? So far, you saw there are many ways to put two numbers together. One way could be to put the numbers in a list of two elements, and implicitly assume the first one is the *real* and the second the *imaginary* part:

```
[1]: c = [3.0, 5.0]
```

Or we could use a tuple:

```
[2]: c = (3.0, 5.0)
```

A problem with the previous representations is that a casual observer might not know exactly the meaning of the two numbers. We could be more explicit and store the values into a dictionary, using keys to identify the two parts:

```
[3]: c = {'real': 3.0, 'imaginary': 5.0}
```

```
[4]: print(c)
{'imaginary': 5.0, 'real': 3.0}
```

```
[5]: print(c['real'])
3.0
```

```
[6]: print(c['imaginary'])
5.0
```

Now, writing the whole record `{'real': 3.0, 'imaginary': 5.0}` each time we want to create a complex number might be annoying and error prone. To help us, we can create a little shortcut function named `complex_number` that creates and returns the dictionary:

```
[7]: def complex_number(real, imaginary):
    d = {}
    d['real'] = real
```

(continues on next page)

(continued from previous page)

```
d['imaginary'] = imaginary
return d
```

```
[8]: c = complex_number(3.0, 5.0)
```

```
[9]: print(c)
{'imaginary': 5.0, 'real': 3.0}
```

To do something with our dictionary, we would then define functions, like for example `complex_str` to show them nicely:

```
[10]: def complex_str(cn):
    return str(cn['real']) + " + " + str(cn['imaginary']) + "i"
```

```
[11]: c = complex_number(3.0, 5.0)
print(complex_str(c))
3.0 + 5.0i
```

We could do something more complex, like defining the phase of the complex number which returns a float:

IMPORTANT: In these exercises, we care about programming, not complex numbers theory. There's no need to break your head over formulas!

```
[12]: import math
def phase(cn):
    """ Returns a float which is the phase (that is, the vector angle) of the
    complex number

        See definition: https://en.wikipedia.org/wiki/Complex\_number#Absolute\_value\_and\_argument
    """
    return math.atan2(cn['imaginary'], cn['real'])
```

```
[13]: c = complex_number(3.0, 5.0)
print(phase(c))
1.0303768265243125
```

We could even define functions that take the complex number and some other parameter, for example we could define the log of complex numbers, which return another complex number (mathematically it would be infinitely many, but we just pick the first one in the series):

```
[14]: import math
def log(cn, base):
    """ Returns another complex number which is the logarithm of this complex
    number

        See definition (accommodated for generic base b):
        https://en.wikipedia.org/wiki/Complex\_number#Natural\_logarithm
    """
    return {'real':math.log(cn['real']) / math.log(base),
            'imaginary' : phase(cn) / math.log(base)}
```

```
[15]: print(log(c, 2))
{'imaginary': 1.4865195378735334, 'real': 1.5849625007211563}
```

You see we got our dictionary representing a complex number. If we want a nicer display we can call on it the `complex_str` we defined:

```
[16]: print(complex_str(log(c, 2)))
1.5849625007211563 + 1.4865195378735334i
```

1.4. Finding the pattern

So, what have we done so far?

- 1) Decided a data format for the complex number, saw that the dictionary is quite convenient
- 2) Defined a function to quickly create the dictionary:

```
def complex_number(real, imaginary):
```

- 3) Defined some function like `phase` and `log` to do stuff on the complex number

```
def phase(cn):
def log(cn, base):
```

- 4) Defined a function `complex_str` to express the complex number as a readable string:

```
def complex_str(cn):
```

Notice that: * all functions above take a `cn` complex number dictionary as first parameter * the functions `phase` and `log` are quite peculiar to complex number, and to know what they do you need to have deep knowledge of what a complex number is. * the function `complex_str` is more intuitive, because it covers the common need of giving a nice string representation to the data format we just defined. Also, we used the word `str` as part of the name to give a hint to the reader that probably the function behaves in a way similar to the Python function `str()`.

When we encounter a new datatype in our programs, we often follow the procedure of thinking listed above. Such procedure is so common that software engineering people though convenient to provide a specific programming paradigm to represent it, called *Object Oriented* programming. We are now going to rewrite the complex number example using such paradigm.

1.5. Object Oriented Programming

In Object Oriented Programming, we usually

1. Introduce new datatypes by declaring a *class*, named for example `ComplexNumber`
2. Are given a dictionary and define how data is stored in the dictionary (i.e. in fields `real` and `imaginary`)
3. Define a way to *construct* specific *instances*, like `3 + 2i`, `5 + 6i` (instances are also called *objects*)
4. Define some *methods* to operate on the *instances* (like `phase`)
5. Define some special *methods* to customize how Python treats *instances* (for example for displaying them as strings when printing)

Let's now create our first *class*.

7.1.4 2. ComplexNumber class

2.1. Class declaration

A minimal class declaration will at least declare the class name and the `__init__` method:

```
[17]: class ComplexNumber:

    def __init__(self, real, imaginary):
        self.real = real
        self.imaginary = imaginary
```

Here we declare to Python that we are starting defining a template for a new *class* called `ComplexNumber`. This template will hold a collection of functions (called methods) that manipulate *instances* of complex numbers (instances are $1.0 + 2.0i$, $3.0 + 4.0i$, ...).

IMPORTANT: Although classes can have any name (i.e. `complex_number`, `complexNumber`, ...), by convention you **SHOULD** use a camel cased name like `ComplexNumber`, with capital letters as initials and no underscores.

2.2. Constructor `__init__`

With the dictionary model, to create complex numbers remember we defined that small utility function `complex_number`, where inside we were creating the dictionary:

```
def complex_number(real, imaginary):
    d = {}
    d['real'] = real
    d['imaginary'] = imaginary
    return d
```

With classes, to create objects we have instead to define a so-called *constructor method* called `__init__`:

```
[18]: class ComplexNumber:

    def __init__(self, real, imaginary):
        self.real = real
        self.imaginary = imaginary
```

`__init__` is a very special method, that has the job to initialize an *instance* of a complex number. It has three important features:

- it is defined like a function, inside the `ComplexNumber` declaration (as usual, indentation matters!)
- it always takes as first parameter `self`, which is an instance of a special kind of dictionary that will hold the fields of the complex number. Inside the previous `complex_number` function, we were creating a dictionary `d`. In `__init__` method, the dictionary instead is automatically created by Python and given to us in the form of parameter `self`
- `__init__` does not return anything: this is different from the previous `complex_number` function where instead we were returning the dictionary `d`.

Later we will explain better these properties. For now, let's just concentrate on the names of things we see in the declaration.

WARNING: There can be only one constructor method per class, and MUST be named `__init__`

WARNING: `init` MUST take at least one parameter, by convention it is usually named `self`

IMPORTANT: `self` is just a name we give to the first parameter. It could be any name our fantasy suggest and the program would behave exactly the same!

If the editor you are using will evidence it in some special color, it is because it is aware of the convention but *not* because `self` is some special Python keyword.

IMPORTANT: In general, any of the `__init__` parameters can have completely arbitrary names, so for example the following code snippet would work exactly the same as the initial definition:

```
[19]: class ComplexNumber:

    def __init__(donald_duck, mickey_mouse, goofy):
        donald_duck.real = mickey_mouse
        donald_duck.imaginary = goofy
```

Once the `__init__` method is defined, we can create a specific `ComplexNumber instance` with a call like this:

```
[20]: c = ComplexNumber(3.0,5.0)
print(c)

<__main__.ComplexNumber object at 0x7f54942ae2b0>
```

What happened here?

init 2.2.1) We told Python we want to create a new particular *instance* of the template defined by `class ComplexNumber`. As parameters for the instance we indicated `3.0` and `5.0`.

WARNING: to create the instance, we used the name of the class `ComplexNumber` following it by an open round parenthesis and parameters like a function call: `c=ComplexNumber(3.0,5.0)` Writing just: `c = ComplexNumber` would NOT instantiate anything and we would end up messing with the *template* “`ComplexNumber`”, which is a collection of functions for complex numbers.

init 2.2.2) Python created a new special dictionary for the instance

init 2.2.3) Python passed the special dictionary as first parameter of the method `__init__`, so it will be bound to parameter `self`. As second and third arguments passed `3.0` and `5.0`, which will be bound respectively to parameters `real` and `imaginary`

WARNING: When instantiating an object with a call like `c=ComplexNumber(3.0,5.0)` you don't need to pass a dictionary as first parameter! Python will implicitly create it and pass it as first parameter to `__init__`

init 2.2.4) In the `__init__` method, the instructions

```
self.real = real
self.imaginary = imaginary
```

first create a key in the dictionary called `real` associating to the key the value of the parameter `real` (in the call is `3.0`). Then the value `5.0` is bound to the key `imaginary`.

IMPORTANT: we said Python provides `__init__` with a special kind of dictionary as first parameter. One of the reason it is special is that you can access keys using the dot like `self.my_key`. With ordinary dictionaries you would have to write the brackets like `self["my_key"]`

IMPORTANT: like with dictionaries, we can arbitrarily choose the name of the keys, and which values to associate to them.

IMPORTANT: In the following, we will often refer to keys of the `self` dictionary with the terms *field*, and/or *attribute*.

Now one important word of wisdom:

!!!!!! VIII COMMANDMENT²³⁴ : YOU SHALL NEVER EVER REASSIGN `self` !!!!!!!

Since `self` is a kind of dictionary, you might be tempted to do like this:

```
[21]: class EvilComplexNumber:
    def __init__(self, real, imaginary):
        self = {'real':real, 'imaginary':imaginary}
```

but to the outside world this will bring no effect. For example, let's say somebody from outside makes a call like this:

```
[22]: ce = EvilComplexNumber(3.0, 5.0)
```

At the first attempt of accessing any field, you would get an error because after the initialization `c` will point to the yet untouched `self` created by Python, and not to your dictionary (which at this point will be simply lost):

```
print(ce.real)
```

`AttributeError: EvilComplexNumber instance has no attribute 'real'`

In general, you *DO NOT* reassign `self` to anything. Here are other example *DON'Ts*:

```
self = ['666'] # self is only supposed to be a sort of dictionary which is passed by
                ↵Python
self = 6       # self is only supposed to be a sort of dictionary which is passed by
                ↵Python
```

init 2.2.5) Python automatically returns from `__init__` the special dictionary `self`

²³⁴ <https://en.softpython.org/commandments.html#VIII-COMMANDMENT>

WARNING: `__init__` must NOT have a `return` statement ! Python will implicitly return `self` !

init 2.2.6) The result of the call (so the special dictionary) is bound to external variable ‘c’:

```
c = ComplexNumber(3.0, 5.0)
```

init 2.2.7) You can then start using c as any variable

```
[23]: print(c)
<__main__.ComplexNumber object at 0x7f54942ae2b0>
```

From the output, you see we have indeed an *instance* of the *class* ComplexNumber. To see the difference between *instance* and *class*, you can try printing the *class* instead:

```
[24]: print(ComplexNumber)
<class '__main__.ComplexNumber'>
```

IMPORTANT: You can create an infinite number of different *instances* (i.e. `ComplexNumber(1.0, 1.0)`, `ComplexNumber(2.0, 2.0)`, `ComplexNumber(3.0, 3.0)`, ...), but you will have only one *class* definition for them (`ComplexNumber`).

We can now access the fields of the special dictionary by using the dot notation as we were doing with the ‘self’:

```
[25]: print(c.real)
3.0
```

```
[26]: print(c.imaginary)
5.0
```

If we want, we can also change them:

```
[27]: c.real = 6.0
print(c.real)
6.0
```

2.3. Defining methods

2.3.1 phase

Let’s make our class more interesting by adding the method `phase(self)` to operate on the complex number:

```
[28]: import unittest
import math

class ComplexNumber:

    def __init__(self, real, imaginary):
        self.real = real
        self.imaginary = imaginary
```

(continues on next page)

(continued from previous page)

```
def phase(self):
    """ Returns a float which is the phase (that is, the vector angle) of the
    ↪complex number

    This method is something we introduce by ourselves, according to the
    ↪definition:
        https://en.wikipedia.org/wiki/Complex_number#Absolute_value_and_argument
    """
    return math.atan2(self.imaginary, self.real)
```

The method takes as first parameter `self` which again is a special dictionary. We expect the dictionary to have already been initialized with some values for `real` and `imaginary` fields. We can access them with the dot notation as we did before:

```
return math.atan2(self.imaginary, self.real)
```

How can we call the method on instances of complex numbers? We can access the method name from an instance using the dot notation as we did with other keys:

```
[29]: c = ComplexNumber(3.0, 5.0)
print(c.phase())
1.0303768265243125
```

What happens here?

By writing `c.phase()`, we call the method `phase(self)` which we just defined. The method expects as first parameter `self` a class instance, but in the call `c.phase()` apparently we don't provide any parameter. Here some magic is going on, and Python implicitly is passing as first parameter the special dictionary bound to `c`. Then it executes the method and returns the desired float.

WARNING: Put round parenthesis in method calls!

When *calling* a method, you MUST put the round parenthesis after the method name like in `c.phase()`! If you just write `c.phase` without parenthesis you will get back an address to the physical location of the method code:

```
>>> c.phase
<bound method ComplexNumber.phase of <__main__.ComplexNumber instance at 0xb465a4cc>
↪>
```

2.3.2 log

We can also define methods that take more than one parameter, and also that create and return `ComplexNumber` instances, like for example the method `log(self, base)`:

```
[30]: import math

class ComplexNumber:

    def __init__(self, real, imaginary):
        self.real = real
        self.imaginary = imaginary
```

(continues on next page)

(continued from previous page)

```
def phase(self):
    """ Returns a float which is the phase (that is, the vector angle) of the
    ↪complex number

    This method is something we introduce by ourselves, according to the
    ↪definition:
        https://en.wikipedia.org/wiki/Complex_number#Absolute_value_and_argument
    """
    return math.atan2(self.imaginary, self.real)

def log(self, base):
    """ Returns another ComplexNumber which is the logarithm of this complex
    ↪number

    This method is something we introduce by ourselves, according to the
    ↪definition:
        (accomodated for generic base b)
        https://en.wikipedia.org/wiki/Complex_number#Natural_logarithm
    """
    return ComplexNumber(math.log(self.real) / math.log(base), self.phase() /_
    ↪math.log(base))
```

WARNING: ALL METHODS MUST HAVE AT LEAST ONE PARAMETER, WHICH BY CONVENTION IS NAMED `self`!

To call `log`, you can do as with `phase` but this time you will need also to pass one parameter for the `base` parameter, in this case we use the exponential `math.e`:

```
[31]: c = ComplexNumber(3.0, 5.0)
logarithm = c.log(math.e)
```

WARNING: As before for `phase`, notice we didn't pass any dictionary as first parameter! Python will implicitly pass as first argument the instance `c` as `self`, and `math.e` as `base`

```
[32]: print(logarithm)
<__main__.ComplexNumber object at 0x7f54942aed30>
```

To see if the method worked and we got back we got back a different complex number, we can print the single fields:

```
[33]: print(logarithm.real)
1.0986122886681098
```

```
[34]: print(logarithm.imaginary)
```

```
1.0303768265243125
```

2.3.3 `__str__` for printing

As we said, printing is not so informative:

```
[35]: print(ComplexNumber(3.0, 5.0))
<__main__.ComplexNumber object at 0x7f54942aefd0>
```

It would be nice to instruct Python to express the number like “ $3.0 + 5.0i$ ” whenever we want to see the `ComplexNumber` represented as a string. How can we do it? Luckily for us, defining the `__str__(self)` method (see bottom of class definition)

WARNING: There are **two** underscores _ before and **two** underscores _ after in `__str__` !

```
[36]: import math

class ComplexNumber:

    def __init__(self, real, imaginary):
        self.real = real
        self.imaginary = imaginary

    def phase(self):
        """ Returns a float which is the phase (that is, the vector angle) of the
        complex number

        This method is something we introduce by ourselves, according to the_
        definition:
            https://en.wikipedia.org/wiki/Complex_number#Absolute_value_and_argument
        """
        return math.atan2(self.imaginary, self.real)

    def log(self, base):
        """ Returns another ComplexNumber which is the logarithm of this complex_
        number

        This method is something we introduce by ourselves, according to the_
        definition:
            (accomodated for generic base b)
            https://en.wikipedia.org/wiki/Complex_number#Natural_logarithm
        """
        return ComplexNumber(math.log(self.real) / math.log(base), self.phase() /_
        math.log(base))

    def __str__(self):
        return str(self.real) + " + " + str(self.imaginary) + "i"
```

IMPORTANT: all methods starting and ending with a double underscore `__` have a special meaning in Python: depending on their name, they override some default behaviour. In this case, with `__str__` we are overriding how Python represents a `ComplexNumber` instance into a string.

WARNING:

Since we are overriding Python default behaviour, it is very important that we follow the specs of the method we are overriding *to the letter*. In our case, the specs for `__str__`²³⁵ obviously state you MUST return a string. **Do read them!**

```
[37]: c = ComplexNumber(3.0, 5.0)
```

We can also pretty print the whole complex number. Internally, `print` function will look if the class `ComplexNumber` has defined a method named `__str__`. If so, it will pass to the method the instance `c` as the first argument, which in our methods will end up in the `self` parameter:

```
[38]: print(c)
```

```
3.0 + 5.0i
```

```
[39]: print(c.log(2))
```

```
1.5849625007211563 + 1.4865195378735334i
```

Special Python methods are like any other method, so if we wish, we can also call them directly:

```
[40]: c.__str__()
```

```
'3.0 + 5.0i'
```

EXERCISE: There is another method for getting a string representation of a Python object, called `__repr__`. Read carefully `__repr__` documentation²³⁶ and implement the method. To try it and see if any difference appear with respect to `str`, call the standard Python functions `repr` and `str` like this:

```
c = ComplexNumber(3,5)
print(repr(c))
print(str(c))
```

QUESTION: Would `3.0 + 5.0i` be a valid Python expression ? Should we return it with `__repr__`? Read again also `__str__` documentation²³⁷

2.4. ComplexNumber code skeleton

We are now ready to write methods on our own. Open Visual Studio Code (no jupyter in part B !) and proceed editing file `ComplexNumber.py`

To see how to test, try running this in the console, tests should pass (if system doesn't find `python3` write `python`):

```
python3 -m unittest ComplexNumber_test.ComplexNumberTest
```

²³⁵ https://docs.python.org/3/reference/datamodel.html#object.__str__

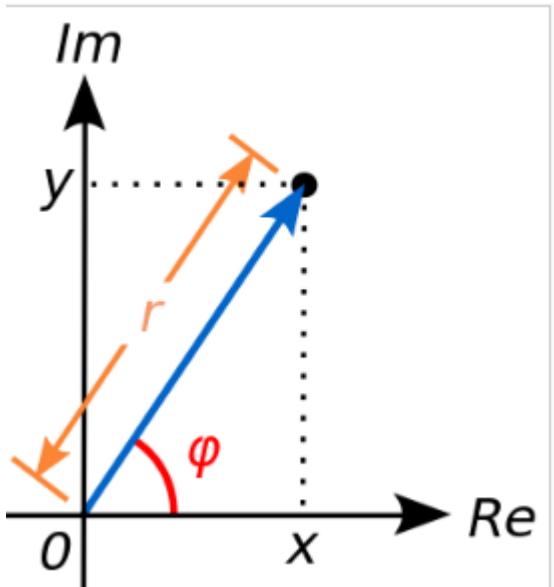

²³⁶ https://docs.python.org/3/reference/datamodel.html#object.__repr__

²³⁷ https://docs.python.org/3/reference/datamodel.html#object.__str__

2.5. Complex numbers magnitude

The *absolute value* (or *modulus* or *magnitude*) of a complex number $z = x + yi$ is

$$r = |z| = \sqrt{x^2 + y^2}.$$

Implement the magnitude method, using this signature:

```
def magnitude(self):
    """ Returns a float which is the magnitude (that is, the absolute value) of the
    complex number

    This method is something we introduce by ourselves, according to the
    definition:
    https://en.wikipedia.org/wiki/Complex_number#Absolute_value_and_argument
    """
    raise Exception("TODO implement me!")
```

To test it, check this test in MagnitudeTest class passes (notice the almost in assertAlmostEquals !!!):

```
def test_01_magnitude(self):
    self.assertAlmostEqual(ComplexNumber(3.0, 4.0).magnitude(), 5, delta=0.001)
```

To run the test, in the console type:

```
python3 -m unittest ComplexNumber_test.MagnitudeTest
```

2.6. Complex numbers equality

Here we will try to give you a glimpse of some aspects related to Python equality, and trying to respect interfaces when overriding methods. Equality can be a nasty subject, here we will treat it in a simplified form.

First of all, try to execute this command, you should get back `False`

```
[41]: ComplexNumber(1,2) == ComplexNumber(1,2)
[41]: False
```

How comes we get `False`? The reason is whenever we write `ComplexNumber(1,2)` we are creating a new object in memory. Such object will get assigned a unique address number in memory, and by default equality between class instances is calculated considering only equality among memory addresses. In this case we create one object to the left of the expression and another one to the right. So far we didn't tell Python how to deal with equality for `ComplexNumber` classes, so default equality testing is used by checking memory addresses, which are different - so we get `False`.

To get `True` as we expect, we need to implement `__eq__` special method. This method should tell Python to compare the fields within the objects, and not just the memory address.

REMEMBER: as all methods starting and ending with a double underscore `__`, `__eq__` has a special meaning in Python: depending on their name, they override some default behaviour. In this case, with `__eq__` we are overriding how Python checks equality. Please review `__eq__` documentation²³⁸ before continuing.

QUESTION: What is the return type of `__eq__` ?

Equality [edit]

Two complex numbers are equal if and only if both their real and imaginary parts are equal. In symbols:

$$z_1 = z_2 \leftrightarrow (\operatorname{Re}(z_1) = \operatorname{Re}(z_2) \wedge \operatorname{Im}(z_1) = \operatorname{Im}(z_2)).$$

- Implement equality for `ComplexNumber` more or less as it was done for `Fraction`

Use this method signature:

```
def __eq__(self, other):
```

Since `__eq__` is a binary operation, here `self` will represent the object to the left of the `==`, and `other` the object to the right.

Use this simple test case to check for equality in class `EqtTest`:

```
def test_01_integer_equality(self):
    """
        Note all other tests depend on this test !
        We want also to test the constructor, so in c we set stuff by hand
    """
    c = ComplexNumber(0,0)
    c.real = 1
    c.imaginary = 2
    self.assertEqual(c, ComplexNumber(1,2))
```

To run the test, in the console type:

²³⁸ https://docs.python.org/3/reference/datamodel.html#object.__eq__

```
python3 -m unittest ComplexNumber_test.EqTest
```

- Beware ‘equality’ is tricky in Python for float numbers! Rule of thumb: when overriding `__eq__`, use ‘dumb’ equality, two things are the same only if their parts are literally equal
- If instead you need to determine if two objects are similar, define other ‘closeness’ functions.
- Once done, check again `ComplexNumber(1, 2) == ComplexNumber(1, 2)` command and see what happens, this time it should give back `True`.

QUESTION: What about `ComplexNumber(1, 2) != ComplexNumber(1, 2)`? Does it behaves as expected?

- (Non mandatory read) if you are interested in the gory details of equality, see
 - How to Override comparison operators in Python²³⁹
 - Messing with hashing²⁴⁰

2.7. Complex numbers `isclose`

Complex numbers can be represented as vectors, so intuitively we can determine if a complex number is close to another by checking that the distance between its vector tip and the the other tip is less than a given delta. There are more precise ways to calculate it, but here we prefer keeping the example simple.

Given two complex numbers

$$z_1 = a + bi$$

and

$$z_2 = c + di$$

We can consider them as close if they satisfy this condition:

$$\sqrt{(a - c)^2 + (b - d)^2} < \text{delta}$$

- Implement the method in `ComplexNumber` class:

```
def isclose(self, c, delta):
    """ Returns True if the complex number is within a delta distance from complex_
    number c.
    """
    raise Exception("TODO Implement me!")
```

Check this test case `IsCloseTest` class pass:

```
def test_01_isclose(self):
    """ Notice we use `assertTrue` because we expect `isclose` to return a `bool`_
    value, and
        we also test a case where we expect `False`
    """
    self.assertTrue(ComplexNumber(1.0, 1.0).isclose(ComplexNumber(1.0, 1.1), 0.2))
    self.assertFalse(ComplexNumber(1.0, 1.0).isclose(ComplexNumber(10.0, 10.0), 0.2))
```

To run the test, in the console type:

²³⁹ <http://jcalderone.livejournal.com/32837.html>

²⁴⁰ <http://www.asmeurer.com/blog/posts/what-happens-when-you-mess-with-hashing-in-python/>

```
python3 -m unittest ComplexNumber_test.IscloseTest
```

REMEMBER: Equality with `__eq__` and closeness functions like `isclose` are very different things. Equality should check if two objects have the same memory address or, alternatively, if they contain the same things, while closeness functions should check if two objects are similar. You should never use functions like `isclose` inside `__eq__` methods, unless you really know what you're doing.

2.8. Complex numbers addition

Complex numbers are **added** by separately adding the real and imaginary parts of the summands.
That is to say:

$$(a + bi) + (c + di) = (a + c) + (b + d)i.$$

Similarly, **subtraction** is defined by

$$(a + bi) - (c + di) = (a - c) + (b - d)i.$$

- a and c correspond to real, b and d correspond to imaginary
- implement addition for `ComplexNumber` more or less as it was done for `Fraction` in theory slides
- write some tests as well!

Use this definition:

```
def __add__(self, other):  
    raise Exception("TODO implement me!")
```

Check these two tests pass in `AddTest` class:

```
def test_01_add_zero(self):  
    self.assertEqual(ComplexNumber(1, 2) + ComplexNumber(0, 0), ComplexNumber(1, 2));  
  
def test_02_add_numbers(self):  
    self.assertEqual(ComplexNumber(1, 2) + ComplexNumber(3, 4), ComplexNumber(4, 6));
```

To run the tests, in the console type:

```
python3 -m unittest ComplexNumber_test.AddTest
```

2.9. Adding a scalar

We defined addition among `ComplexNumbers`, but what about addition among a `ComplexNumber` and an `int` or a `float`?

Will this work?

```
ComplexNumber(3, 4) + 5
```

What about this?

```
ComplexNumber(3,4) + 5.0
```

Try to add the following method to your class, and check if it does work with the scalar:

```
[42]: def __add__(self, other):
    # checks other object is instance of the class ComplexNumber
    if isinstance(other, ComplexNumber):
        return ComplexNumber(self.real + other.real, self.imaginary + other.
                             ↪imaginary)

    # else checks the basic type of other is int or float
    elif type(other) is int or type(other) is float:
        return ComplexNumber(self.real + other, self.imaginary)

    # other is of some type we don't know how to process.
    # In this case the Python specs say we MUST return 'NotImplemented'
    else:
        return NotImplemented
```

Hopefully now you have a better add. But what about this? Will this work?

```
5 + ComplexNumber(3,4)
```

Answer: it won't, Python needs further instructions. Usually Python tries to see if the class of the object on left of the expression defines addition for operands *to the right* of it. In this case on the left we have a `float` number, and `float` numbers don't define any way to deal to the right with your very own `ComplexNumber` class. So as a last resort Python tries to see if your `ComplexNumber` class has defined also a way to deal with operands *to the left* of the `ComplexNumber`, by looking for the method `__radd__`, which means *reverse addition*. Here we implement it :

```
def __radd__(self, other):
    """ Returns the result of expressions like other + self """
    if (type(other) is int or type(other) is float):
        return ComplexNumber(self.real + other, self.imaginary)
    else:
        return NotImplemented
```

To check it is working and everything is in order for addition, check these tests in `RaddTest` class pass:

```
def test_01_add_scalar_right(self):
    self.assertEqual(ComplexNumber(1,2) + 3, ComplexNumber(4,2));

def test_02_add_scalar_left(self):
    self.assertEqual(3 + ComplexNumber(1,2), ComplexNumber(4,2));

def test_03_add_negative(self):
    self.assertEqual(ComplexNumber(-1,0) + ComplexNumber(0,-1), ComplexNumber(-1,-1));
```

2.10. Complex numbers multiplication

Multiplication and division [\[edit\]](#)

The multiplication of two complex numbers is defined by the following formula:

$$(a + bi)(c + di) = (ac - bd) + (bc + ad)i.$$

In particular, the square of the imaginary unit is -1 :

$$i^2 = i \times i = -1.$$

- Implement multiplication for `ComplexNumber`, taking inspiration from previous `__add__` implementation
- Can you extend multiplication to work with scalars (both left and right) as well?

To implement `__mul__`, implement definition into `ComplexNumber` class:

```
def __mul__(self, other):
    raise Exception("TODO Implement me!")
```

and make sure these tests cases pass in `MulTest` class:

```
def test_01_mul_by_zero(self):
    self.assertEqual(ComplexNumber(0, 0) * ComplexNumber(1, 2), ComplexNumber(0, 0));

def test_02_mul_just_real(self):
    self.assertEqual(ComplexNumber(1, 0) * ComplexNumber(2, 0), ComplexNumber(2, 0));

def test_03_mul_just_imaginary(self):
    self.assertEqual(ComplexNumber(0, 1) * ComplexNumber(0, 2), ComplexNumber(-2, 0));

def test_04_mul_scalar_right(self):
    self.assertEqual(ComplexNumber(1, 2) * 3, ComplexNumber(3, 6));

def test_05_mul_scalar_left(self):
    self.assertEqual(3 * ComplexNumber(1, 2), ComplexNumber(3, 6));
```

7.1.5 3. MultiSet

You are going to implement a class called `MultiSet`, where you are only given the class skeleton, and you will need to determine which Python basic datastructures like `list`, `set`, `dict` (or combinations thereof) is best suited to actually hold the data.

In math a multiset (or bag) generalizes a set by allowing multiple instances of the multiset's elements.

The multiplicity of an element is the number of instances of the element in a specific multiset.

For example:

- The multiset `a, b` contains only elements `a` and `b`, each having multiplicity 1
- In multiset `a, a, b, a` has multiplicity 2 and `b` has multiplicity 1
- In multiset `a, a, a, b, b, b, a` and `b` both have multiplicity 3

NOTE: order of insertion does not matter, so `a, a, b` and `a, b, a` are the same multiset, where `a` has multiplicity 2 and `b` has multiplicity 1.

```
[43]: from multiset_sol import *
```

7.1.6 3.1 `__init__` add and get

Now implement *all* of the following methods: `__init__`, add and get:

```
def __init__(self):
    """ Initializes the MultiSet as empty."""
    raise Exception("TODO IMPLEMENT ME !!!")

def add(self, el):
    """ Adds one instance of element el to the multiset

        NOTE: MUST work in O(1)
    """
    raise Exception("TODO IMPLEMENT ME !!!")

def get(self, el):
    """ Returns the multiplicity of element el in the multiset.

        If no instance of el is present, return 0.

        NOTE: MUST work in O(1)
    """
    raise Exception("TODO IMPLEMENT ME !!!")
```

Testing

Once done, running this will run only the tests in `AddGetTest` class and hopefully they will pass.

Notice that `multiset_test` **is followed by a dot and test class name** `.AddGetTest`:

```
python3 -m unittest multiset_test.AddGetTest
```

7.1.7 3.2 `removen`

Implement the following `removen` method:

```
def removen(self, el, n):
    """ Removes n instances of element el from the multiset (that is, reduces el's
    multiplicity by n)

        If n is negative, raises ValueError.
        If n represents a multiplicity bigger than the current multiplicity, raises
        LookupError

        NOTE: multiset multiplicities are never negative
        NOTE: MUST work in O(1)
    """

```

Testing: `python3 -m unittest multiset_test.RemovenTest`

4. Challenges

Have a look at the OOP Matrix Challenge²⁴¹

[]:

7.2 OOP Matrix Challenge

7.2.1 Download exercises zip

Browse files online²⁴²

We want to model operations on IMMUTABLE matrices, the object oriented way.

You have a generic interface called `Matrix` in file `matrix.py`, and you have to implement two descendants of the interface, `DenseMatrix` and `SparseMatrix`.

IMPORTANT: work in group and share tests!

You will make a lot of mistakes, some hard to debug: help yourself by writing test cases, we also invite you to share the tests (not the solutions!) with your fellow students.

Please note there are many cornercases, even if stuff *seems* to work there will probably occasions where it fails - you won't probably be able to find them all on your own.

7.2.2 What to do

- unzip exercises in a folder, you should get something like this:

```
oop
matrix.py
oop-matrix-chal.ipynb
.
.
```

You can ignore the notebook, and edit `.py` files in Visual Studio Code.

7.2.3 DenseMatrix

Let's begin with the simpler implementation, which is `DenseMatrix`: you will code it by storing data inside lists of lists.

Create a new file `dense_matrix.py` and declare a class `DenseMatrix` which inherits from `Matrix`. Copy inside all the methods definitions from `Matrix`.

```
from matrix import Matrix

class DenseMatrix(Matrix):
    """ A Matrix represented internally as a list of lists
```

(continues on next page)

²⁴¹ <http://sciprog.davidleoni.it/oop/oop-matrix-chal.html>

²⁴² <https://github.com/DavidLeoni/sciprog-ds/tree/master/oop>

(continued from previous page)

When creating it from list of lists, perform a DEEP COPY of the input and store it inside a private field you will call _cells (use ONE underscore)

7.2.4 Constructors and printing

Generally first methods we implement are the constructor and methods to show the class content such as `__str__` and `__repr__`. All methods are documented in the `matrix.py` interface, let's see now the constructor. Copy paste the following inside your `DenseMatrix` class.

```
def __init__(self, *args):
    """Initializes the Matrix with either:

    One argument: a list of lists
    Three arguments: number of rows
                    number of columns
                    a list of cell triplets (row_index,col_index,value)
                    - if number of rows or columns is less than indeces found
                      in triplets, raise ValueError

    In both cases, provided data must allow the creation of a matrix with
    at least one row and a column, otherwise raise ValueError
    """
    raise Exception("Should be implemented in a descendant of Matrix!")
```

Constructor as list of lists

We see the the constructor takes the special `*args` argument, which means it can accept a variable number of arguments. To check for the two cases, you might write something like this:

```
class DenseMatrix(Matrix):
    def __init__(self, *args):

        if len(args) == 1:    # list of lists
            rows = args[0]
            # do something ...
        elif len(args) == 3:
            n,m,triplets = args
            # do something
        else:
            raise ValueError('Expected one or three args!')
```

You can start by handling only the one argument case, which we will interpret as a list of lists. You can store a **deep** copy of the list of lists in a private field you can call `_cells`. Why should we store a deep copy? It's a form a so-called defensive-programming: if we store a copy, it's less likely that a user of our class will later mess with the instance internal data. If we store the data in a field beginning with one underscore `_`, we will signal external users we do not want them to directly access it (notice if they really want they will still be able to do it)

```
[1]: from dense_matrix_chal_sol import *
from sparse_matrix_chal_sol import *
```

```
[2]: dma = DenseMatrix([ [0, 6, 8, 0],  
                      [0, 0, 0, 5],  
                      [9, 0, 7, 0] ])
```

```
[3]: dma
```

```
[3]: DenseMatrix([[0, 6, 8, 0], [0, 0, 0, 5], [9, 0, 7, 0]])
```

```
[4]: type(DenseMatrix)
```

```
[4]: type
```

str and repr

Implement `__str__` and `__repr__`

```
def __str__(self):  
    """ RETURN a nice human-readable formatted string, possibly like this:  
  
        Matrix [ [5,2,6,3],  
                  [8,4,7,4],  
                  [2,1,9,8] ]  
  
    - substitute Matrix with the descendant class name  
    - NOTE: sometimes this representation is impractical (i.e. sparse matrices  
            with large n/m), in that case use another format of your choice  
    """  
    raise Exception("Should be implemented in a descendant of Matrix!")  
  
def __repr__(self):  
    """ RETURN one-line string representing a Python expression which would recreate  
    ↪the atrix  
    """  
    raise Exception("Should be implemented in a descendant of Matrix!")
```

```
[5]: str(dma)
```

```
[5]: 'DenseMatrix [ [0, 6, 8, 0]\n                 [0, 0, 0, 5]\n                 [9, 0, 7, 0] ]'
```

```
[6]: print(dma)
```

```
DenseMatrix [ [0, 6, 8, 0]  
                  [0, 0, 0, 5]  
                  [9, 0, 7, 0] ]
```

```
[7]: repr(dma)
```

```
[7]: 'DenseMatrix([[0, 6, 8, 0], [0, 0, 0, 5], [9, 0, 7, 0]])'
```

```
[8]: dma
```

```
[8]: DenseMatrix([[0, 6, 8, 0], [0, 0, 0, 5], [9, 0, 7, 0]])
```

constructor as list of triplets

Now extend the constructor to handle also the list of triplets case:

```
[9]: dmb = DenseMatrix(3, 4, [(0, 1, 6), (0, 2, 8), (1, 3, 5), (2, 0, 9), (2, 2, 7)])
```

```
[10]: dmb
```

```
[10]: DenseMatrix([[0, 6, 8, 0], [0, 0, 0, 5], [9, 0, 7, 0]])
```

```
[11]: print(dmb)
```

```
DenseMatrix [ [0, 6, 8, 0]
              [0, 0, 0, 5]
              [9, 0, 7, 0] ]
```

7.2.5 shape

Implement shape method:

```
def shape(self):
    """RETURN the number of rows and columns as a tuple
    """

```

```
[12]: dma.shape() # NOTE the ()
```

```
[12]: (3, 4)
```

7.2.6 Brackets operator

Override the square bracket operator by reimplementing the method `__getitem__`

IMPORTANT: Read carefully Python documentation²⁴³!!

```
def __getitem__(self, key):
    """Overrides default bracket access behaviour.
    key is whatever the user passes within the brackets, in our case
    we want user to be able to write

    my_mat[2,5] to access element at row 2 and column 5

    NOTE 1: if the user types 2,5 inside the brackets, Python will actually
            generate a TUPLE (2,5) so that is the key type you should
            accept (a tuple of *exactly two* integers)
    NOTE 2: Since this method signature is defined by Python documentation:

    https://docs.python.org/3/reference/datamodel.html#object.__getitem__

    you MUST write it respecting ALL the indications of the docs, in particular
    think also about what should happen in undesired scenarios when
    the user enters a key of wrong type, wrong value, etc as described
    in the documentation
    """

```

²⁴³ https://docs.python.org/3/reference/datamodel.html#object.__getitem__

```
[13]: print(dma)
DenseMatrix [ [0, 6, 8, 0]
              [0, 0, 0, 5]
              [9, 0, 7, 0] ]
```

```
[14]: dma[0,1]
```

```
[14]: 6
```

```
[15]: dma[0,2]
```

```
[15]: 8
```

Negative indeces should also be supported:

```
[16]: dma[0,-3]
```

```
[16]: 6
```

7.2.7 nonzero

```
def nonzero(self):
    """Return a list of triplets (row index, column index, value) of non-zero
    ↪cells,
    in no particular order.
    """
```

Since we stored the rows in a private field `_cells`, we have to offer users other ways to access data. For example, by calling `nonzero()` method users should be able to obtain non-zero values, as a list of triplets with row index, column index and value of cells. You might wonder what the utility is, after we already implemented the brackets operator: the reason will become clearer when you start implementing methods that need to visit a generic `Matrix`, like the following ones.

```
[17]: print(dma)
DenseMatrix [ [0, 6, 8, 0]
              [0, 0, 0, 5]
              [9, 0, 7, 0] ]
```

```
[18]: dma.nonzero()
```

```
[18]: [(0, 1, 6), (0, 2, 8), (1, 3, 5), (2, 0, 9), (2, 2, 7)]
```

7.2.8 isclose

Implement this method:

DO NOT MAKE ASSUMPTIONS ABOUT other CLASS!

In the implementation, use `other` like if it were a generic `Matrix`, it might not always be a `DenseMatrix`. So the only way to access elements will be either by using the brackets operator or by calling `nonzero()`

```
def isclose(self, other, delta):
    """ RETURN True if each cell in this matrix is within a delta distance
        from other Matrix. RETURN False if any cell couple differs more than_
        ↪delta.

        - if matrices have different dimensions, raise ValueError
    """

```

[19]:

```
print(dma)

DenseMatrix [ [0, 6, 8, 0]
              [0, 0, 0, 5]
              [9, 0, 7, 0] ]
```

[20]:

```
dmd = DenseMatrix([ [0,      5.9,     8,      0],
                    [0,          0, 0.1,      5],
                    [9.15, -0.1,      7, 0.1] ])
```

dma.isclose(dmd, 0.2)

[20]:

```
True
```

[21]:

```
dma.isclose(dmd, 0.05)
```

[21]:

```
False
```

7.2.9 Equality

Override == operator:

[22]:

```
dma = DenseMatrix([ [0, 6, 8, 0],
                    [0, 0, 0, 5],
                    [9, 0, 7, 0] ])

dmb = DenseMatrix(3, 4, [(0, 1, 6), (0, 2, 8), (1, 3, 5), (2, 0, 9), (2, 2, 7)])
```

dma == dmb

[22]:

```
True
```

Notice in this case, since we want in general to check equality *to the last bit*, we will want to check that `other` is actually a `DenseMatrix`, otherwise we will return `False`

[23]:

```
dma == 'ciao'
```

[23]:

```
False
```

Equality with a different shape should just return `False`, without raising exceptions:

[24]:

```
dma == DenseMatrix([[2, 4],
                    [9, 3]])
```

[24]:

```
False
```

Equality with different numbers:

```
[25]: dmc = DenseMatrix([ [1,2,3,4],  
                         [6,7,8,9],  
                         [10,11,12,13] ])  
dma == dmc  
[25]: False
```

7.2.10 Sum

Override + operator so can sum other Matrix instances:

DO NOT MAKE ASSUMPTIONS ABOUT other CLASS!

In the implementation, use `other` like if it were a generic `Matrix`, it might not always be a `DenseMatrix`. So the only way to access elements will be either by using the brackets operator or by calling `nonzero()`

```
[26]: dma = DenseMatrix([ [0,6,8,0],  
                         [0,0,0,5],  
                         [9,0,7,0] ])  
  
dmc = DenseMatrix([ [1,2,3,4],  
                     [6,7,8,9],  
                     [10,11,12,13] ])
```

```
[27]: print(dma + dmc)  
  
DenseMatrix [ [1, 8, 11, 4]  
              [6, 7, 8, 14]  
              [19, 11, 19, 13] ]
```

Note `dma` and `dmc` where **not** modified:

```
[28]: print(dma)  
  
DenseMatrix [ [0, 6, 8, 0]  
              [0, 0, 0, 5]  
              [9, 0, 7, 0] ]
```

```
[29]: print(dmc)  
  
DenseMatrix [ [1, 2, 3, 4]  
              [6, 7, 8, 9]  
              [10, 11, 12, 13] ]
```

7.2.11 Multiplication

Override * operator so we can multiply by a scalar:

```
[30]: print(dma * 2)

DenseMatrix [ [0, 12, 16, 0]
              [0, 0, 0, 10]
              [18, 0, 14, 0] ]
```

DO NOT MAKE ASSUMPTIONS ABOUT other CLASS!

In the implementation, use `other` like if it were a generic `Matrix`, it might not always be a `DenseMatrix`. So the only way to access elements will be either by using the brackets operator or by calling `nonzero()`

Again multiplication by a scalar does **not** modify the original:

```
[31]: print(dma)

DenseMatrix [ [0, 6, 8, 0]
              [0, 0, 0, 5]
              [9, 0, 7, 0] ]
```

Multiplying a scalar by a matrix should also work:

```
[32]: print(2 * dma)

DenseMatrix [ [0, 12, 16, 0]
              [0, 0, 0, 10]
              [18, 0, 14, 0] ]
```

Again original `dma` was not changed:

```
[33]: print(dma)

DenseMatrix [ [0, 6, 8, 0]
              [0, 0, 0, 5]
              [9, 0, 7, 0] ]
```

Matrix vector multiplication

Next implement support for multiplication of a matrix by a properly dimensioned vector **on the right**, which must have the same number of rows as the matrix number of columns:

matrix	vector	result
\j 012		
i 0 aaa	v0	a00*v0 + a01*v1 + a02*v2
1 aaa	v1	a10*v0 + a11*v1 + a12*v2
2 aaa	v2	a20*v0 + a21*v1 + a22*v2
3 aaa		a30*v0 + a31*v1 + a32*v2

The result will have the same number of rows as the matrix.

DO NOT MAKE ASSUMPTIONS ABOUT other CLASS!

In the implementation, use `other` like if it were a generic `Matrix`, it might not always be a `DenseMatrix`. So the only way to access elements will be either by using the brackets operator or by calling `nonzero()`

```
[34]: dmveca = DenseMatrix([[1],[2],[3],[4]])
```

```
[35]: print(dmveca)
```

```
DenseMatrix [ 1]
             [2]
             [3]
             [4] ]
```

```
[36]: print(dma)
```

```
DenseMatrix [ [0, 6, 8, 0]
              [0, 0, 0, 5]
              [9, 0, 7, 0] ]
```

```
[37]: print(dma * dmveca)
```

```
DenseMatrix [ [36]
              [20]
              [30] ]
```

Multiplication by a vector does **not** modify the originals:

```
[38]: print(dmveca)
```

```
DenseMatrix [ 1]
             [2]
             [3]
             [4] ]
```

Notice dimensions must be compatible, this should **not** work:

```
>>> print(dma*DenseMatrix([[1],[2]]))

-----
TypeError                                 Traceback (most recent call last)
<ipython-input-33-bc850efec5f1> in <module>()
      1 print(dma*DenseMatrix([[1],[2]]))

TypeError: unsupported operand type(s) for *: 'DenseMatrix' and 'DenseMatrix'
```

Vector matrix multiplication

Next implement support for multiplication of a matrix by a properly dimensioned horizontal vector **on the left**, which must have the same number of columns as the matrix number of rows:

```
ector matrix result

\j  012  0123 0123
i    vvv 0 aaaa rrrr
```

(continues on next page)

(continued from previous page)

```

1 aaaa
2 aaaa

res = a00*v0+a10*v1+a20*v2, a01*v0+a11*v1+a21*v2, a02*v0+a12*v1+a22*v2,
      ↪a03*v0+a13*v1+a23*v2

```

The result will have the same number of columns as the matrix.

DO NOT MAKE ASSUMPTIONS ABOUT other CLASS!

In the implementation, use `other` like if it were a generic `Matrix`, it might not always be a `DenseMatrix`. So the only way to access elements will be either by using the brackets operator or by calling `nonzero()`

```
[39]: print(dma)

DenseMatrix [ [0, 6, 8, 0]
              [0, 0, 0, 5]
              [9, 0, 7, 0] ]
```

```
[40]: dmvecb = DenseMatrix([[1,2,3]])
```

```
[41]: print(dmvecb * dma)
DenseMatrix [ [27, 6, 29, 10] ]
```

Matrix matrix multiplication

This would be the general problem but for the purposes of this challenge, it is **not mandatory** to support multiplication by a matrix, **even if they have compatible dimensions**:

```

>>> print(dma*DenseMatrix([[3,2],
                           [3,7],
                           [2,8],
                           [9,3],]]))

-----
TypeError                                         Traceback (most recent call last)
<ipython-input-34-ed1ad440c418> in <module>()
      2                               [3,7],
      3                               [2,8],
----> 4                               [9,3],]))
```

```
TypeError: unsupported operand type(s) for *: 'DenseMatrix' and 'DenseMatrix'
```

7.2.12 SparseMatrix

If you've arrived so far, congratulations, that was quite a journey. But only half of it! We've seen matrices as lists of lists for a long time, let's now see if we can save some space. Many real-world matrices have often most cells set to zero, so it would be convenient to avoid storing in memory those cells, and reserve space only for non-zero valued cells. There are many ways to do it (see [Wikipedia²⁴⁴](#)), in this challenge we will adopt the simplest which is the so-called [Dictionary of Keys²⁴⁵](#) (DOK in short). DOK consists of a dictionary that maps (row, column)-pairs to the value of the elements. Elements that are missing from the dictionary are assumed to be zero.

Now we can see the real reason why we supported also a constructor with triplets: if the goal of using a SparseMatrix is to avoid creating huge tables in memory, initializing it with a list of lists would defeat the purpose! In what follows, sometimes we may still use the list of lists initialization, but that would only be for clarity purposes.

7.2.13 Sparse constructors and printing

Create a new file `sparse_matrix.py` and copy inside this with the method definitions you find in `matrix.py` as done before.

```
from matrix import Matrix

class SparseMatrix(Matrix):
    """ A SparseMatrix is a matrix which contains very few non-zero elements.

        In this implementation, storage is modelled as a dictionary of keys (DOK in
        ↪short),
        where each key is a tuple of cell coordinates which maps to a non-zero cell
        ↪value.

    NOTE: *NEVER* store zero-valued cells.
    """

```

Follow the same implementation order as before, so start with the constructor `__init__`, `__str__` and `__repr__` overrides. Note this time our class implementation will have a **dictionary** as private `_cells` field.

With sparse matrices we can have a big 30x20 matrix and occupy very little memory:

```
[42]: sma = SparseMatrix(30,20, [(26,17,3), (24,11,5)])
```

You can save the shape inside a private `_shape` field.

Since shape can be much bigger than actual data, with `__str__` you must show the internal dictionary **and** the shape:

```
[43]: print(sma)

SparseMatrix {
    (24, 11): 5,
    (26, 17): 3
}
shape: (30, 20)
```

`__repr__` will show the triplets constructor:

```
[44]: repr(sma)
```

²⁴⁴ https://en.wikipedia.org/wiki/Sparse_matrix

²⁴⁵ [https://en.wikipedia.org/wiki/Sparse_matrix#Dictionary_of_keys_\(DOK\)](https://en.wikipedia.org/wiki/Sparse_matrix#Dictionary_of_keys_(DOK))

```
[44]: 'SparseMatrix(30,20, [(24, 11, 5), (26, 17, 3)])'
```

```
[45]: sma
```

```
[45]: SparseMatrix(30,20, [(24, 11, 5), (26, 17, 3)])
```

7.2.14 Sparse shape

Implement `shape()`:

```
[46]: sma.shape()      # note the round brackets
```

```
[46]: (30, 20)
```

7.2.15 Sparse Brackets operator

Override the square bracket operator by reimplementing the method `__getitem__`

CAREFUL!

Even more than before, you have to super-carefully read [Python documentation²⁴⁶!!](#)

To respect Python documentation, this time you can't rely on built-in errors and features of lists as you probably did in the `DenseMatrix` case, so you will have to write a lot of `if` that check for various possible errors (bad types, values, etc) and raise the appropriate errors (`IndexError`, `TypeError`, `KeyError`, etc)

Implement brackets operator:

```
[47]: sma[24,11]
```

```
[47]: 5
```

```
[48]: sma[26,17]
```

```
[48]: 3
```

```
[49]: sma[29,3]    # shouldn't explode
```

```
[49]: 0.0
```

Support negative numbers:

```
[50]: sma[-6,11]
```

```
[50]: 5
```

```
[51]: sma[29,-2]
```

```
[51]: 0.0
```

²⁴⁶ https://docs.python.org/3/reference/datamodel.html#object.__getitem__

7.2.16 Sparse nonzero

This is very important, as it allows iterating the data structure in an efficient way - depending on the shape, trying all the couples i, j with the square brackets might be prohibitively costly.

```
[52]: sma.nonzero()  
[52]: [(24, 11, 5), (26, 17, 3)]
```

7.2.17 Sparse isclose

Be careful to write generic code, and **avoid iterating all possible i,j couples** - you should only look into nonzero ones.

```
[53]: print(sma)  
SparseMatrix {  
    (24, 11): 5,  
    (26, 17): 3  
}  
shape: (30, 20)  
  
[54]: sma.isclose(SparseMatrix(30,20, [(24, 11, 4.9), (26, 17, 3.1)]), 0.2)  
[54]: True  
  
[55]: sma.isclose(SparseMatrix(30,20, [(24, 11, 4.9), (26, 17, 3.1)]), 0.05)  
[55]: False  
  
[56]: sma.isclose(SparseMatrix(30,20, [(24, 11, 4.9), (26, 17, 3.1), (13,18,0.5)]), 0.2)  
[56]: False  
  
[57]: sma.isclose(SparseMatrix(30,20, [(24, 11, 4.9), (26, 17, 3.1), (13,18,0.1)]), 0.2)  
[57]: True  
  
[58]: sma.isclose(SparseMatrix(30,20, [(24, 11, 4.9), (26, 17, 3.1), (13,18,-0.1)]), 0.2)  
[58]: True
```

The interesting part comes when we try `isclose` with *another* class, like `DenseMatrix`. If you wrote general enough code, only assuming `other` is a generic `Matrix` the following should work without particular effort:

```
[59]: smp = SparseMatrix([[1, 0, 3],  
                      [4, 5, 0]])  
dmp = DenseMatrix([[1.1, 0.1, 2.9],  
                  [4.05, 4.9, -0.05]])  
  
[60]: smp.isclose(dmp, 0.2)  
[60]: True  
  
[61]: smp.isclose(dmp, 0.05)  
[61]: False
```

```
[62]: dmp.isclose(smp, 0.2)
```

```
[62]: True
```

```
[63]: dmp.isclose(smp, 0.05)
```

```
[63]: False
```

7.2.18 Sparse equality

Be careful to write generic code, and **avoid iterating all possible i,j couples** - you should only look into nonzero ones.

```
[64]: sma
```

```
[64]: SparseMatrix(30,20, [(24, 11, 5), (26, 17, 3)])
```

```
[65]: smb = SparseMatrix(30,20, [(24, 11, 5), (26, 17, 3)])
```

```
[66]: sma == smb
```

```
[66]: True
```

```
[67]: sma == smb
```

```
[67]: True
```

```
[68]: sma == SparseMatrix(30,20, [(24, 11, 5), (26, 17, 123)])
```

```
[68]: False
```

```
[69]: sma == SparseMatrix(30,20, [(24, 11, 5), (26, 17, 3), (5,10,6)])
```

```
[69]: False
```

Equality among different types should always be `False`, even if they descend from the same ancestor:

```
[70]: SparseMatrix([[1,2],[3,4]]) == DenseMatrix([[1,2],[3,4]])
```

```
[70]: False
```

```
[71]: DenseMatrix([[1,2],[3,4]]) == SparseMatrix([[1,2],[3,4]])
```

```
[71]: False
```

7.2.19 Sparse sum

Be careful to write generic code, and **avoid iterating all possible i,j couples** - you should only look into nonzero ones.

```
[72]: smq = SparseMatrix([[1,2,0],  
                      [4,0,6]])  
dmq = DenseMatrix([[0,8,0],  
                  [0,7,3]])
```

```
[73]: print(smq + smq)
```

```
SparseMatrix {  
    (0, 1): 4,  
    (1, 2): 12,  
    (1, 0): 8,  
    (0, 0): 2  
}  
shape: (2, 3)
```

Again the interesting bit is when you try summing among different classes:

```
[74]: print(smq + dmq)  
  
SparseMatrix {  
    (0, 1): 10,  
    (1, 2): 9,  
    (1, 0): 4,  
    (0, 0): 1,  
    (1, 1): 7  
}  
shape: (2, 3)
```

```
[75]: print(dmq + smq)  
  
DenseMatrix [ [1, 10, 0.0]  
              [4, 7.0, 9] ]
```

7.2.20 Sparse multiplication

As always, be careful writing general code, and avoid iterating all possible i,j couples - you should only look into nonzero ones.

Sparse matrix vector multiplication

```
[76]: smq = SparseMatrix([[1,0,3],  
                      [4,5,0]])  
  
smvecq = SparseMatrix([[1],  
                      [0],  
                      [3]])  
print(smq * smvecq)  
  
SparseMatrix {  
    (1, 0): 4.0,  
    (0, 0): 10  
}  
shape: (2, 1)
```

Let's try mixing types:

```
[77]: dmq = DenseMatrix([[1,0,3],  
                      [4,5,0]])  
  
dmvecq = DenseMatrix([[1],  
                      [0],  
                      [0]])
```

(continues on next page)

(continued from previous page)

```
[3]]
print(smq * dmvecq)

SparseMatrix {
    (1, 0): 4,
    (0, 0): 10
}
shape: (2, 1)
```

```
[78]: print(dmq * smvecq)

DenseMatrix [ [10.0]
              [4.0] ]
```

Sparse vector matrix multiplication

```
[79]: smvecr = SparseMatrix([[1,2,0]])

smr = SparseMatrix([ [0, 6, 8, 0],
                     [0, 0, 0, 5],
                     [9, 0, 7, 0] ])

print(smvecr * smr)

SparseMatrix {
    (0, 1): 6,
    (0, 3): 10,
    (0, 2): 8.0
}
shape: (1, 4)
```

Let's mix types:

```
[80]: dmvecr = DenseMatrix([[1,2,0]])

dmr = DenseMatrix([ [0, 6, 8, 0],
                     [0, 0, 0, 5],
                     [9, 0, 7, 0] ])

print(smvecr * dmr)

SparseMatrix {
    (0, 1): 6,
    (0, 3): 10,
    (0, 2): 8.0
}
shape: (1, 4)
```

```
[81]: print(dmvecr * smr)

DenseMatrix [ [0, 6, 8, 10] ]
```

7.3.1 Introduction

Life's too easy so let's complicate it, shall we?

Are you ready to fight the invisible enemy of computational complexity? If not, please read the references first:

- Luca Bianco's Introduction to algorithms slides²⁴⁸
- Luca Bianco's Algorithms and complexity slides²⁴⁹
- Python DS Chapter 2.6: Algorithm analysis²⁵⁰

7.3.2 List performance

Python lists are generic containers, they are useful in a variety of scenarios but sometimes their performance can be disappointing, so it's best to know and avoid potentially expensive operations. Table from the Python DS book Chapter 2.6: Lists²⁵¹:

Operation	Big-O Efficiency	Operation	Big-O Efficiency
index []	$O(1)$	in (contains)	$O(n)$
index assignment	$O(1)$	get slice [x:y]	$O(k)$
append	$O(1)$	del slice	$O(n)$
pop()	$O(1)$	set slice	$O(n+k)$
pop(i)	$O(n)$	reverse	$O(n)$
extend(lb)	$O(m)$	la + lb	$O(n+m)$
insert(i,item)	$O(n)$	sort	$O(n \log n)$
del operator	$O(n)$	multiply	$O(nk)$
remove	$O(n)$	min	$O(n)$
iteration	$O(n)$	max	$O(n)$
len(lst)	$O(1)$	sum	$O(n)$
equality	$O(n)$

²⁵¹ <https://runestone.academy/runestone/books/published/pythonds/AlgorithmAnalysis/Lists.html>

Fast or not?

Given a list x of n characters, for each of the following expressions, try giving the complexity:

1. `x[n // 2]`

2. `x[n // 2] = 'd'`

3. `x.append('c')`

4. `x.insert(0, 'd')`

5. `x + x`

6. `x[3:5]`

7. `x.sort()`

8. `len(x)`

9. `x.pop(1)`

10. `x.pop(-1)`

11. `'z' in x`

12. `x.extend(1000)`

13. `y = [c for c in x]`

14. `list(range(n)) == list(range(n))`

Sublist iteration performance

get slice time complexity is $O(k)$, but what about memory? It's the same!

So if you want to iterate a part of a list, beware of slicing! For example, depending on Python version you have, slicing a list like this can occupy much more memory than necessary:

```
[1]:                                #           memory occupied
r = range(1000) # Python 2 creates a list:          O(n)
                 # Python 3 creates a 'range' object: O(1)

#           same for range slices: memory occupied
print([2*y for y in r[100:200]]) # x[100:200] Python 2      O(k)
                                 #           Python 3      O(1)

[200, 202, 204, 206, 208, 210, 212, 214, 216, 218, 220, 222, 224, 226, 228, 230, 232, 234, 236, 238, 240, 242, 244, 246, 248, 250, 252, 254, 256, 258, 260, 262, 264, 266, 268, 270, 272, 274, 276, 278, 280, 282, 284, 286, 288, 290, 292, 294, 296, 298, 300, 302, 304, 306, 308, 310, 312, 314, 316, 318, 320, 322, 324, 326, 328, 330, 332, 334, 336, 338, 340, 342, 344, 346, 348, 350, 352, 354, 356, 358, 360, 362, 364, 366, 368, 370, 372, 374, 376, 378, 380, 382, 384, 386, 388, 390, 392, 394, 396, 398]
```
